New Zealand Flax in the Isle of Man.—It may interest your readers to learn that at the present time there are twelve large clumps of New Zealand Flax, *Phormium tenax*, in full flower-spike in the Mooragh Park, Ramsey, Isle of Man, and that about seventy other clumps of a few years later growth are in fine healthy condition, and will in the course of a year or two add very materially to the attractions of these beautiful pleasure grounds. The history of these plants and their appearance so far from their native habitat savours somewhat of the romantic. In the summer of 1904 the Town Clerk of Ramsey received by post a package of seed from a resident in Christchurch, New Zealand. The sender signed himself "J. J. D.," a native of Ramsey, who left his home sixty years before. He had read of the development of the Mooragh Estate and the formation of the Mooragh park and lake, and was desirous of contributing something ornamental that would be unique, and that would attract and interest visitors to his native town. The mystery of "J. J. D." was as good as a Yankee guessing competition, and after the lapse of two years the problem was solved by Dr. F. S. Tellet, J.P., who remembered a blacksmith of the name of J. J. Dailey leaving Ramsey for New Zealand when he was quite a young lad. In the meantime the Town Clerk had sent out packages of the seed to about a dozen leading gardeners in the island; but the only successful grower was Mr. Thomas Martin, gardener to Dr. J. M. Barbour, M.O.H., Ramsey. Mr. Martin raised a dozen strong plants, and these were removed to the Mooragh Park, where they immediately took root, and have developed into the present fine clumps. In October, 1906, the Town Clerk received a further quantity of Flax seed from Mr. Dailey, and he thought he would try if it were possible to grow the seed in the open without the aid of artificial heat. In this he was entirely successful, for a handful of the seed sown in a box in the open produced about eighty plants, seventy of which were transferred to the Mooragh Park. He retained about ten for his own garden, where the soil and situation were different. In both instances the plants are growing remarkably well, and it is evident from these facts that the climate of the Isle of Man is suitable for the growth of this ornamental plant. Six of the above plants are carrying over forty spikes, measuring over ten feet in height. On August 20 I collected ripe seed in perfect order, fit for sowing at any time. I enclose a photograph, which may be of interest

to other readers of your valuable paper. The plant there is in a large bed of *Nemesia Suttonii*, which has been greatly admired all the summer.—JOSEPH MILBURN, *Mooragh, Ramsey, Isle of Man*.

A KIRKCUDBRIGHTSHIRE GARDEN.

WHEN staying recently for a few days at Knockallan, near Castle Douglas, I had the privilege of visiting several scenes of great beauty and horticultural fascination, which will long abide in the regions of remembrance. Until, under the guidance of a cultured companion, I saw for the first time the grounds and gardens of Mallance, I had no conception that a mansion with such a charming environment of stately trees and exquisite flowers existed in the fair region to which Knockallan belongs. To me, I confess, it was at once a surprise of the most charming nature, and a veritable revelation of what Art can accomplish for the ennobling of Nature. The day, though tropical in its atmospheric conditions, was otherwise a near approximation to perfection, for it was, in the language of the saintly George Herbert,

"calm and bright,

The bridal of the Earth and Sky;"

and the scene was also worthy of the splendid affluence of sunlight whereby it was revealed. The extensive flower garden was especially radiant with its green environment of majestic woods, amid the coolness of whose shadows it was a kind of rapture at intervals to rest. For on such a brilliant day it is quite possible to be, like the immortal Prince of Denmark, "too much in the sun." And I sometimes dream that, in this respect, the flowers we so greatly love and so tenderly and patiently cultivate are not unlike ourselves; for though they seem to rejoice in the bright presence of the "Gardener of the world" (as Robert Louis Stevenson called the sun), yet they are never so beautiful as in the early morning or the hushful twilight, when they are in partial shade. Seldom have I seen *Begonias*, *Pelargoniums*, or the marvelously coloured *Antirrhinums* luxuriating in any gardens in such a perfect light.

The accomplished head-gardener at Mallance (Mr. Stewart) has everything there in as artistic and impressive form as it is possible for a lover of Nature to conceive, and that is saying much. He was, in his earlier years of probation, he informs me, with that consummate botanist and arboriculturist Sir Herbert Maxwell, and an experience of this kind means not only exacting industry and elaboration in every department, but also intense horticultural conscientiousness.

These grand attributes are everywhere reflected in the gardens of Mallance, where fruit and flowers of every description are grown with earnest attention, and consequently with splendid success. Never since the memorable days when I used to visit the king of pomologists, the late Mr. Thomas Francis Rivers, at his great nurseries in Hertfordshire have I seen Apples and Pears anywhere so effectively cultivated under glass. It only remains to be added to these fragmentary and inadequate observations that botanical trees and tropical plants of every impressive description in these beautiful gardens are grandly grown.

DAVID R. WILLIAMSON.

Manse of Kirkmaiden, Wigtownshire, N.B.

PRESERVING NUTS FOR WINTER USE.

THIS season there are abundant crops of the Nut tribe, such as Walnuts, Spanish Chestnuts, Filberts and Cob Nuts. Now that all foodstuffs should be economically treated, hints on the best methods of preserving Nuts will be useful. Too often those with no experience attempt to preserve these Nuts in the worst possible place—a dry room—with the Nuts thinly spread on the floor or shelves. Some will place the Nuts in a vessel and cover them with salt, which usually ends in the Nuts being quite unfit for use.

The best place is outdoors, burying them in proper receptacles 2 feet under the surface where they are in an equable, low temperature secure from air, and under such circumstances they

Walnuts.—When these fall from the trees naturally or with an easy shake of the branches, the husks should be removed and the Nuts dried in the sun in the open, or under cover. The shells should be thoroughly cleansed from the fibrous portions of the husks, which sometimes adhere to the shells. Some persons wash them, but this is neither necessary nor wise. Take an ordinary corn sack or coarse bag, place the Nuts inside, and with one person at each end of the sack holding the corners roll the Nuts briskly backwards and forwards until they are quite clean; then thoroughly dry them, which should not take more than two or three days to effect. If they are forcibly dried or exposed too long to the sun or air, the kernels are apt to shrivel, which means a loss of bulk, freshness and flavour. Any quantity up to a bushel can be placed in one vessel, although rather less might be safer.

Filberts and Cob Nuts should be quite ripe when gathered and thoroughly dried with the

behold. This Broom is really a hybrid, the result of crossing *C. purgans* with *C. albus*, and plants can be purchased cheaply. In common with other members of the family, it will thrive in very poor sandy soil; but this must not be taken as an indication that it does not appreciate a more generous diet. In fact, it will do well in almost any kind of soil that is well drained. Early November is a good time to plant, or the early part of March if more convenient; but the young plants should be obtained in pots, so as to avoid excessive disturbance of the roots. H.

ANNUAL FLOWERS TO SOW IN AUTUMN.

ALTHOUGH many hardy annual flowers are now sown in the autumn, there is no reason why, under certain conditions, this phase of their cultivation should not be much more widely extended. Nature, in her wisdom, provides for the sowing of nearly all seeds as soon as they are ripe, and, were the conditions under which they ripened perfectly natural, no better course could be adopted. But gardening is an "art that doth mend Nature," and many of the flowers, or at least their progenitors, that we grow in our gardens are natives of far warmer climes than ours; hence it follows that we must, if we will grow them successfully, save the seeds until the frost and damp of winter are past.

On the other hand, there are a number of annual flowers which are quite hardy with us, or at least sufficiently so to enable a large percentage of seedlings to survive an ordinary winter, and it is the sowing of such that I would advise in the autumn. But let no one imagine that all the "hardy annuals" of the seedsmen's catalogues can be successfully sown at this season. By some miraculous reading of the English language, "hardy" means to the seedsmen those kinds of annuals that may be successfully grown from seed onwards during late spring and summer without the aid of glass. Thus we find the Indian Cress, or so-called *Nasturtium*, one of the most tender annuals that we know of, classed as "hardy." Strange as it may seem, this word of warning is necessary, as I have on more than one occasion found seeds of such tender plants being sown in the autumn.

Even though we select our kinds aright, the vagaries of our English climate, as well as the vast difference in the character of the soil, must be fully borne in mind, and both on occasion can prove exceedingly troublesome. Over our climate we have no control; consequently in sowing annual flowers in autumn, which means that the seedlings will have to stand out all the winter, we are taking a sporting chance, and one that usually gives us a fair return for our outlay of time and expenditure, which, by the way is usually insignificant. With soil, however it is different. Here we know what we have to contend with, and it would be fallacious in the extreme to sow annuals now in soil that is mainly composed of clay. Hardy though the plants might be, they would surely succumb to the cold moisture that would ever be present in the soil in too great a quantity during the short, dark days of our long winter months. This, again, is where the gardener's art mends Nature. Instead of following her plan of sowing seeds as soon as

A YOUNG PLANT OF THE EARLY FLOWERING BROOM, *CYTISUS PRÆCOX*.

come out quite plump and full of flavour even six or twelve months afterwards. A low cellar answers fairly well if the floor is of brick and inclined to be damp. No matter where they are stored, it is important that the Nuts be thoroughly prepared before they are transferred to their final quarters, and unless they are stored in a fit condition, success cannot be assured.

The Receptacles, too, in which they are placed must be of the right kind. Some employ close-fitting wooden boxes, and with care they answer the purpose. The best utensil, however, to employ is an earthenware vessel, glazed inside, with a tightly fitting lid, or, in other words, an ordinary bread pannikin. Failing this, a very good substitute can be made with an ordinary flower-pot, blocking up the hole at the bottom with cement and having a closely fitting slate lid. Give the outside of the pot a couple of coats of paint to eliminate its porosity, and thus prevent the ingress of moisture to the Nuts.

husks still on, packing them loosely in similar vessels.

Spanish Chestnuts should have the outer, spiny husks removed, the Nuts dried and packed closely in a similar way.

Swanmore, Hants.

E. MOLYNEUX.

THE EARLY FLOWERING BROOM.

THERE are few more beautiful plants in the garden during the late days of spring than the early flowering Broom (*Cytisus præcox*). This hardy shrub usually opens its creamy white flowers at the end of April or the first week in May, just when the last of the trumpet Daffodils are waning and the Poets have taken up the display. As will be seen in the accompanying illustration, the blossoms are produced in great profusion, each slender, graceful shoot being almost covered. The flowers last in good condition for about three weeks; but even at other seasons the shrub is pleasing to

they are ripe, he keeps them safe and dry until the more genial days of spring, when his clay soil has become warmed by the sun and in a more porous and better condition for plant life.

But there are a multitude of gardens the soil of which is composed largely of sand, or a thin layer of soil over chalk, and here it is that the hardy annuals which I will name presently may be sown in September or the first week in October. Indeed, the superiority of autumn-sown plants over those sown early in April in these gardens is astonishing. Not only do they commence to flower much earlier, but they are more sturdy and give far better results over a much longer period. The soil may be dug well and made moderately firm previous to sowing, and the surface ought to be raked down so as to get a fine tilth, as the seeds of most flowers are small. The one evil that must, however, be guarded against is deep sowing. This is where Nature teaches us a lesson. In very few instances indeed does she provide for deep sowing, the majority of seeds having to be content with what little soil may be washed on to them by rain or blown over them by wind. Many of the failures that are attributed to other causes are really due to too deep sowing. For most kinds of annual seeds the merest covering of fine soil is sufficient, and even for Sweet Peas an inch is enough at this season. The necessity for thin sowing and early thinning of the seedlings cannot be too strongly emphasised. It is most important in the spring, but doubly so at this season, because the young plants have subsequently to withstand the cold of winter, and it is imperative that they be as sturdy and robust as possible.

The sowing of Sweet Peas in autumn is now very largely adopted in gardens where the soil is not heavy clay, and it is an annual that invariably gives the best results from such sowings. But it is a flower by itself, a queen among annuals, and its cultivation is so well understood and so different from that required by ordinary annuals that there is no need to go into details here. Other annuals that may be sown during the next few days are Godetias and Clarkias, *Nemophila insignis*—if cats are not plentiful—*Silene pendula*, *Candytuft*, *Bartonia aurea*, *Virginian Stock*, *Cornflowers*, *Shirley Poppies*, *Eschscholtzias*, *Limnanthes Douglasii*, *Collomia coccinea*, *Larkspurs*, annual *Chrysanthemums*, *Ionopsidium acaule* and *Erysimum*.

There are doubtless several others that would survive the winter in many gardens, and the wise gardener will ever be experimenting in this direction. This finding out for one's self what is best for any special garden or locality is one of the greatest joys experienced in the cultivation of flowers.

S. X.

CLIMBING ROSES WITH LARGE FLOWERS.

ALTHOUGH the Rambler Roses of Dorothy Perkins and American Pillar types are very beautiful and have their use in the garden, there are many owners who naturally desire others which have large specimen blooms suitable for cutting. The list of such kinds is not nearly so limited as one might at first imagine. One of the strongest growing is Conrad F. Meyer, a sweet-scented Hybrid Rugosa Rose with pale pink flowers. Other good varieties are Bouquet d'Or, an improved Gloire de Dijon; Ards Rover,

ASTER VIMINEUS LOVELY, A NEW DWARF MICHAELMAS DAISY
WITH LILAC-PINK FLOWERS. (See page 486.)

crimson; Florence Haswell Veitch, brilliant scarlet crimson, sweetly scented, but not quite so strong growing as some; Longworth Rambler, cherry red; Billiard et Barré, yellow; Mme. Alfred Carrière, white, very fragrant; Dr. Rouges, red, shaded orange, petals curiously twisted; Lady Waterlow, though often used for bedding, will make growths 10 feet long; and Johanna Sebus, reddish blush, very fragrant. In addition to these, there are the climbing and rambling forms of such good, large-flowered Roses as Mrs. W. J. Grant, Liberty, Frau Karl Druschki, Lady Ashtown, La France, Caroline Testout, Kaiserin Augusta Victoria, Captain Christy and Papa Gontier. Although, as a rule, these do not ramble quite so freely as Longworth Rambler and Conrad F. Meyer, they are admirably adapted for covering

arches, the fronts of garden houses, pillars or rustic poles. In many instances the flowers are quite equal to those of the dwarfier forms, particularly if disbudding is resorted to when the flower-buds are small.

G. W.

TULIPS IN BEDS.

IT is an obvious truism to state that Tulips may be planted in beds, either by themselves or in combination with other plants. "You pays your money and you takes your choice." Being neither a thought reader nor a prophet, I am unable to say what that choice will be, for a grand mass of one colour, say, of Couleur Cardinal or Farncombe Sanders, is every bit as beautiful as a combination consisting of a groundwork of *Alyssum saxatilis* with dot plants of some dark late Tulip like Fra Angelico or Zanzibar. At one time I must candidly confess that I had decided leanings to the all one colour and one variety style; now I am much more like the old lady of Oxford and Cambridge Boat Race fame who used religiously to deck her stall every year with both light and dark blue, and who in consequence had to undergo a certain amount of chaff. The famous dead-heat year came and the laugh was on the other side. "Right at last! Right at last! Ha ha!" So I must write of both, for the two have run a dead-heat, and I want to be right at last. First, then, about the "all Tulips" beds. There are a few kinds, both in the earlies and in the May flowerers, that seem to stand out from the others as being peculiarly suited for massing.

Among these are the following: Early single—Prince of Austria, orange red; Couleur Cardinal, dark rich crimson; Vermilion Brilliant, bright scarlet; Keizerskroon, red, edged yellow; Scarlet Mammoth, midseason red of dazzling brightness; and Enchantress, ruby crimson edged pale buff. Early double—Schoonoord, pure white; Murillo, blush white; Vuurbaak, red. Darwin and Cottage—I limit myself to the dwarfier-growing kinds, as it is only in very large beds that the tallest ones look well: Millet, deep rich crimson; Clara Butt, rosy pink; Inglescombe Yellow, soft yellow; Thérèse Schwartz, lavender and mauve; Pygmalion, reddish violet; Corydon, silvery grey; Loveliness, soft rosy pink; Rev. H. H. D'ombrain, brilliant geranium red; Carnation, pointed pink and white; Marksman, brilliant scarlet; and Pompadour, long bloom, glowing crimson. Another way in which beds of all Tulips may be filled is by mixtures, but unless the space is a fairly large one, they do not show to advantage. The best way to manage smaller beds is by using confined assortments,

say, all mauves with just half-a-dozen dark ones, or all pinks, or all reds. A third way is by associating different heights of more or less the same shade. In the French branching Tulip, Mons. S. Mottet, we have, as it were, the mixing already done, for a bed of these gives exactly the effect that I have tried to indicate, and, besides, it is like Prince of Austria, in that it gives a double feast of colour, being white at first, but, like a good meerscham, colouring with age and becoming a pretty deep rose.

To keep the balance I now pass on to combinations of Tulips with other plants. In this connection may I be allowed to thank Messrs. Dickson and Robinson of Manchester for their most instructive exhibit of Tulip combinations at this year's Chelsea Show. In my opinion we want more of this style of thing. The flower-loving public want suggestions upon this very point. It is not always an easy thing to fix up really good combinations. Colours, habits, times of flowering, surroundings, have all to be considered, as well as the individual taste of the owner of the garden. I know what thought my good old friend the Rector of Acton Burnell, near Shrewsbury, gives to his spring bedding, and I know how well his care repays him. If he happens to read this article, he will see how I have drawn upon his store of knowledge in penning these suggestions, just as Messrs. Dickson and Robinson will see some of their Chelsea ideas here reproduced. One point occurs to me as worth mentioning before I begin the lists, and that is the background against which the Tulips will be seen when viewed from a distance. This is rather different from what I meant when I wrote above that the surroundings of the beds must be considered. By that I intended to convey the idea of the more immediate beds, plants, walls, or house of which the special one we are going to fill will be a near neighbour, and which I supposed to be observed from close quarters. Both the near and far view require consideration.

List of Combinations with Other Plants.—(1) A good dark blue Forget-me-not, such as

Indigo Queen or Miss Willmott, with Prince of Austria. (2) Queen Victoria Forget-me-not with variegated-leaved Yellow Prince. (3) Double Arabis with Macrospeila. (4) Dr. Mules or some other dark blue-purple Aubrietia with Picotee Tulip, and with or without an edging of the small variegated-leaved Funkia undulata. (5) Alyssum saxatile with a dark Darwin, such as The Sultan, Fra Angelico or Jubilee. (6) A reddish purple Aubrietia such as Whitewell Gem with Erguste or the striped Dainty Maid. (7) A band or edging of double white Arabis with any tall Cottage or Darwin Tulip in the centre. A soft pinky rose

such as Loveliness or a soft reddy orange such as Orange King are better than more violent contrasts. (8) A good strain of long-spurred Aquilegia, with tall red Tulips such as gesneriana major or Isis as dot plants. The Columbine will not be in flower, but the red popping up from among the feathery foliage and flower-buds is most effective. (9) A good Forget-me-not with Bouton d'Or and an edging of the *old original* Violetta. (10) Funkia Sieboldii (fol. var.) with King Harold (Darwin). (11) Mixed shades of crimson Polyanthus with either Solfatare or Ellen Willmott Tulips. (12) Maggie Mott Viola with a mixture

(19) Cheap Daffodils like princeps, which can be cut away after flowering, planted alternately and fairly closely with late Tulips gives two distinct displays, and as the boy said when his mother reproved him for being so wasteful as to eat butter with his jam, "No, ma, the same bit of bread does for both." (20) Wallflowers and tall late-flowering Tulips. Twenty-firstly and lastly, for the sermon is getting long, and at a seven or a multiple of that number seems in this connection not altogether an appropriate place at which to stop—for combinations are almost like the sand on the seashore in number—a broad edge of Maggie Mott with a central mass of Frans Hals or Pygmalion Tulips. A Dutch friend of mine always says when anything very much takes his fancy, "Fine! Fine!" I say the same of this, "Fine! Fine!" It is the set piece at the firework exhibition, and, like it, ends my display of aerial bedding. JOSEPH JACOB.

ANTIRRHINUMS OR SNAPDRAGONS GROWING IN A DRY WALL.

PLANTING IN DRY WALLS.

WHERE gardens are on hilly sites, giving opportunities for the making and planting of retaining walls, nothing is more satisfactory or encouraging than the rapidity with which they become clothed with more or less permanent vegetation. When flower borders are planted, however well and fully, there is some degree of their appearance till the plants have become established; but the conditions of wall planting are so favourable—the roots finding a cool, rambling region among the stones, the collars protected from winter cold and the heads in full air and sunlight—that they appear to establish themselves at once and more effectively. Planted a year and a half ago, and less in the case of the biennials, the wall surfaces, as shown in the illustrations, now present a fully clothed appearance, and, although the soil is of a poor, sandy character, the plants are in full growth and vigour. Masses of the grey Santolina set off the purple of Catmint

of lavender and mauve Tulips, such as La Tristesse, Erguste and Euterpe, with an odd Turenne or two, or some other dark variety for contrast. (13) Glyceria spectabilis with Clara Butt. (14) Galega Hartlandii (for greenery, and when the Tulips are over for flower) with a tall-growing variety such as Faust, Farncombe Sanders or Pride of Haarlem. (15) Leghorn Bonnet with the bronze foliage of an Astilbe. (16) Cerastium tomentosum with the dark Morales. (17) Orange and yellow Polyanthus Primroses with Golden Bronze (Toison d'Or) Tulip. (18) Erysimum Allionii with Remembrance or Ronald Gunn.

and the white and yellow of the Tree Lupines just above. In a year or two, when some plants of Cistus cyprus are grown—a few blooms show above the second patch of Santolina—the picture will be still more complete. Snapdragons are true wall plants, and should be used largely in the joints of dry walling. Besides those grown as annuals, it is well to make a second sowing about midsummer. This gives small plants to put into the wall joints towards the end of September, or at any time during the month when there has been a good rain. In many places they are too tender to survive in the open ground,

but the wall joint gives so much shelter and such a comforting degree of dryness in winter that the plants do well and are in bloom from the end of May and all through June, the flowering season being then taken up by plants made from cuttings and wintered in frames; these again being followed by the spring-sown plants. Foxgloves and Mulleins are also grand plants in walls where these are in gardens large enough for them not to be out of scale. But even in small places one need not be afraid to plant large things in walls. Many a planted wall is monotonous in effect because its occupants are small things only.

GERTRUDE JEKYLL.

THE CROCUSES OF AUTUMN AND WINTER.

ALTHOUGH they cannot be compared with the brilliant yellow, blue and white Crocuses that blow so freely in the early spring months, the species that naturally flower from October onwards until the dainty little *C. susianus* opens its blossoms in February are by no means devoid of interest. Indeed, some of the more showy ones form a delightful feature of the outdoor garden in the fast waning days of the year, and when kissed by the autumn or winter sun reveal hidden beauties that surpass the vivid hues of their spring brethren. For some inexplicable reason these autumn and winter Crocuses are not grown in many gardens; indeed, one might safely say that they are rarely met with outside the gardens of enthusiastic hardy plant lovers; yet they are by no means difficult to cultivate. It is true that some of the best are rather expensive, at least compared with the spring varieties, but not sufficiently so to account for the neglect that they suffer in most gardens. To gain the full beauty of the autumn and winter Crocuses, a sunny position, and if possible one sheltered from boisterous winds, should be chosen. It is only when the sun meets the flowers that they open and so display their beautiful venation of the segments and the rich colour of stigma and anthers. Wind, too, often causes much damage to the blossoms, as they are more fragile than those of many other plants. Ideal positions can, however, be found in most gardens without much difficulty. Where a narrow border runs alongside the west or south of the dwelling-house, the Crocuses under notice will find a happy home; or it may be that nooks bearing these aspects are available in the rock garden or to the front of the shrubbery border; any place, in fact, where the corms can be left undisturbed. Of equal importance to aspect and shelter is the question of soil. Not that these Crocuses are over-fastidious, but they resent excessive or stagnant moisture. A well-drained soil that is rather on the sandy side suits them

best, but any good soil that is not water-logged can have sand added to it for these flowers, should it be at all lacking in that substance. In fact, where the soil is at all heavy, it is best to place a layer of sand under and over the corms at planting-time, which is usually early in August, though July is better if corms can be obtained then. They may, however, be successfully planted as late as the first or second week in September, though so late a date is not advisable if it can be avoided. Although it is now too late to plant these autumn Crocuses, it will be of interest to draw attention to the best, as the earliest will soon be opening their blossoms. Those named as winter-flowering sorts can still be successfully planted, though the earlier the corms are consigned to Mother Earth the better. The depth to plant the corms is a moot point. I believe Mr. E. A. Bowles, whom his numerous friends style the "Crocus King," advocates planting about three inches deep, and under his clever

But I would advocate keeping each kind by itself. Thus in the rock garden a whole nook should be devoted to one, two or three dozen corms of one species, and the same course of grouping should be adopted where a border by the dwelling-house or other building is being planted. The following are all good autumn and winter flowering Crocuses that are not very expensive, and which are not difficult to grow: Autumn—*asturicus*, pale to deep mauve, with violet stripes at the base; *hyemalis* Foxii, white, veined rich purple, with yellow interior; *longiflorus*, one of the best, with beautiful soft lilac flowers; *pulchellus*, lavender blue, with white anthers; *Salzmanni*, lilac, with violet stripes; *sativus*, the Saffron Crocus, purple lilac, striped violet, with brilliant orange stigma; *speciosus*, the best of all autumn Crocuses, the bright blue flowers being particularly showy; *Aitchisonii*, a large-flowered variety of *speciosus*; *zonatus*, lilac, with orange zone. Winter—*biflorus*, white, striped violet;

A DRY WALL SUCCESSFULLY PLANTED WITH LUPINES, NEPETA MUSSINII AND OTHER LARGE-GROWING FLOWERS.

management they do remarkably well. For the ordinary mortal, however, such a course would lead to failure with many of the choicest kinds, and the safest plan I am convinced is to plant as shallow as possible; 1½ inches of soil on the corms is ample, and it ought to be in a finely crushed condition. The arrangement of the corms calls for some consideration. It must be admitted that single plants dotted about indiscriminately are neither effective nor pleasing, and it is to colonies that we must look for good effects. How large these colonies shall be will depend upon the space at disposal and the quantity that is to be grown

chrysanthus, yellow, variable; *etruscus*, pale lavender; *Imperati*, a beautiful violet-coloured Crocus; *Sieberi*, pale lavender blue; and *vitellinus*, yellow, with orange scarlet stigma. D. W. S.

LIFTING AND STORING BEET ROOT.

BEETROOT must not be allowed to remain in the beds to get frozen; but it is unwise to lift and store it too soon. All the roots must be so treated that they will retain their juices. Violent pulling of the roots from the soil must be avoided. When

A SUSSEX TRUG MAKER PREPARING WOOD FOR THE BASKETS.

this is done the tops are unduly bruised and the roots are scratched; thus bleeding occurs and loss of colour. We prefer to store Beetroot in sand; it closes tightly upon the roots and excludes air; the sand remains cool and does not heat, neither does it contaminate the roots. The latter should be lifted by means of a strong garden fork, with which the soil should be removed from the roots. Twist off the tops 3 inches above the crown. If cut, the sap-vessels are left open and bleeding may be excessive. Pack the roots in layers in sand in a cool shed; have the tops and the crowns just free of the sand. The heaps may be long and narrow, tapering to a point from a 3-feet-wide base, or pyramid-shaped. If severe frosts occur, cover the heaps with mats or straw. It is a good plan to grade the Beetroot—that is, to place the small ones in one heap, the medium in another, and the largest by themselves; then when required they can be used accordingly.

TRUG BASKETS.

ALL workers are apt to take too much for granted the tools of their trade, without which their own handiwork would be difficult, if not impossible. Yet there is no little romance in their making, and this is especially true of the gardener's trug basket. "Trug," no doubt, stands for trough, and one would have supposed that these shallow, trough-like wooden baskets—obviously convenient as they are for garden use—must have been used from time immemorial.

In fact, however, they were invented by one Thomas Smith of Hurstmonceaux, East Sussex, no longer ago than the end of the eighteenth century, and in that village and by his descendants most of the trugs used in all quarters of the world are still made. No common deftness is needed for their making, and a man may turn out six dozen in a week. The various processes are not split up among many, in the wearisome way of most industries, but each worker makes his baskets complete from start to finish. The thin, wide strips of wood which are the main feature of the trug are of Sallow (or "Sally" as they call it locally), of which Hurstmonceaux has long been cleared, and the supplies now come from East Kent. The splitting of the logs needs skill, and is done with a special long-handled axe, which has its cutting edge at right angles to the haft instead of parallel with it. The strips are then shaped with a draw-knife, the workman sitting on a "dolly," which is an ingenious combination of seat and adjustable vice. The rims of the baskets, two stiffening keels and the handles are of narrow strips of Ash, which are soaked in water to make them pliable before the parts are nailed together. The basket is finished by two strips of wood nailed across the bottom to serve as legs, but these are sometimes omitted. No doubt there are many curious trades like trug-making which minister to the gardener, all un-

conscious of the sources of his comfort, but there can be few so localised as that of Hurstmonceaux.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Heliotrope Mrs. J. W. Lowther.—A very handsome, free-flowering and heavily trussed variety, which, with a dwarf and vigorous habit of growth, should commend itself to all. It is most powerfully scented. From Messrs. William Cutbush and Sons, Highgate, N.

Aster Amellus Arethusa.—Quite a valuable addition to the Italian Starworts, the warm rose pink colouring being of a most welcome shade. Exhibited by Messrs. T. S. Ware, Limited, Feltham.

Aster vimineus Lovely.—A most beautiful and graceful sort, with elegant, horizontally disposed sprays arranged in well-branched panicles. The colour is lilac pink. (See illustration on page 483.) Shown by Messrs. H. J. Jones, Limited, Lewisham.

Salvia Griegii.—The flowers are about the size of those of *S. azureus grandiflora*, and coloured a brilliant scarlet. It is a very profuse flowering variety of neat habit of growth. It will be welcomed, too, by those who appreciate fragrant-leaved plants. Shown by Mr. Amos Perry, Enfield.

Pilostegia viburnoides.—A striking and somewhat remarkable new shrub from China, having slightly channelled, lanceolate, glossy green, leathery leaves 4 inches or 5 inches long, and large terminal clusters of creamy flowers. The species is quite new to cultivation, and if, when established, it proves to be an autumn-flowering subject, it will possess a value of its own. From the Hon. Vicary Gibbs, Elstree, Herts.

Dahlia Lord Kitchener (Cactus).—A very handsome exhibition variety of rich crimson scarlet shade. From Mr. Shoesmith, Woking.

Dahlia Neptune (Cactus).—The colour is rosy cerise, in a large and shapely exhibition variety.

Dahlia W. E. Peters (Cactus).—This is of rich wine red shade, in a finely incurving and handsome variety.

Dahlia Melody (Cactus).—A handsome variety coloured a heavy cream. These three were exhibited by Messrs. James Stredwick and Sons, St. Leonards.

Dahlia Lowfield Star.—This is another good addition to the new race of "Star" or Cosmea-flowered Dahlias, the rosy colour being of considerable warmth and much decorative merit. From Messrs. J. Cheal and Sons, Crawley.

Dahlia Barbara Purier (Pompon).—Quite of model shape, medium size and the purest white. From Messrs. Keynes, Williams and Co., Salisbury.

The above-mentioned Dahlias were adjudicated upon by a joint committee of the National Dahlia Society and the Royal Horticultural Society, and therefore carry the first-class certificate of the former and the award of merit of the latter.

We crave the indulgence of our readers and the exhibitors of the foregoing novelties for the colour descriptions given. The exhibits were seen under artificial light in the lower regions of the Great Central Hall, Westminster, the military having occupied the hall at Vincent Square; hence the colours were not seen to advantage. All the awards were made on the 22nd ult.

FINISHED TRUG OR GARDEN BASKETS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Permanent Vines.—If ripe Grapes are expected in May, it will be necessary to prune and prepare the Vines with as little delay as possible, so that the house may be shut up and the Vines started gently by the first week in November. In pruning old Vines it is not advisable to cut the wood too hard back, but to be guided by the state of the buds, leaving three or more eyes when necessary in order to make certain of a crop. Although the Vines may not look so neat when treated in this way, one cannot afford to sacrifice a crop for the sake of appearance. After pruning has been carefully performed, all loose bark should be removed and the Vines washed with soft soapy water, but carefully avoid bruising the buds. If mealy bug is present, the trellis and walls may be carefully washed with paraffin. When this work is finished, the surface of the border ought to be lightly pricked up and the surface soil removed to make room for a top-dressing of new soil, which may be mixed with old lime rubble and finely crushed bones. No water need be applied for the present, but, when forcing commences, the border should be examined and, if necessary, a good soaking of clear soft water applied.

Early Pot Vines.—If very early Grapes are desired, pot Vines may be forced in preference to permanent Vines, as they can be subjected to more heat than it is prudent to apply to Vines which have taken several years to bring to a fit state for extra early forcing. These should be cut to the required length at once and placed in an exposed position until the time arrives for forcing.

Melons.—Plants which are swelling their fruits will require careful attention with regard to watering and ventilating. Some stimulant may be applied in the form of artificial manure, lightly sprinkled over the bed, previous to watering with clear soft water. Ventilate freely when the weather permits, and leave a little air on during the night, with sufficient fire-heat to keep the temperature at 75°.

Plants Under Glass.

Mignonette.—Another sowing may be made now in 4-inch pots, which should be well drained. Rich loam and sifted lime rubble will suit the purpose well, and should be made tight in the pots previous to sowing the seeds. Young plants from previously sown seed may be thinned to four plants in a 5-inch pot. Place small Bamboo twigs to keep them in an upright position, and grow them quite near the roof glass in a well-ventilated greenhouse and fully exposed to the sun.

Cyclamen.—Seeds may now be sown with a view to producing young plants for flowering next season. The soil should consist of loam and leaf-mould in equal parts, and ought to be mixed with sufficient silver sand to keep it from becoming sour. Sow the seeds thinly and press well into the soil. Afterwards cover lightly with fine soil. Cyclamen plants for winter flowering are now well rooted, and will benefit by light top-dressings of artificial manure. Clay's Fertilizer mixed with fine sifted soil suits them well as a top-dressing. Very little shading will be necessary now, but the ventilators should be freely opened when external conditions are favourable.

Calceolarias.—Plants in small pots should now be transferred to their flowering pots. Protect from sun and keep the pit closed until they become re-established, after which air should be given in sufficient quantity to keep them from becoming drawn. Fumigate the pit as it becomes necessary for the destruction of insects.

The Flower Garden.

Delphiniums.—In cases where these plants have become too large and the soil exhausted, the present is a suitable time to divide them and make new plantations. Those which flowered early and were cut down a few weeks ago will be making numerous young growths and roots, which will soon take hold of the new soil which has been prepared for them. In making bold

clumps of Delphiniums, overcrowding should be avoided, as this is detrimental to the constitution of the plants.

The Rose Garden.

Climbing Roses.—The present is a suitable time to remove old flowering stems in order to make room for young, healthy shoots to flower next season. A space of 8 inches should be allowed between strong young shoots, as overcrowding is almost sure to produce red spider and other pests during the summer.

The Rock Garden.

Increasing Plants.—The dripping weather experienced during the last few weeks will have caused many of the plants which have been cut over to make fresh growths. In many cases these new shoots may be used as cuttings, for it is not too late to increase the stock of young plants which may be necessary to fill vacancies in the spring. Aubrietias, Arabis, Dianthi and Phloxes will all make roots if inserted in small pots of sandy soil and placed in a close frame or under a bell-glass. Campanulas may also be increased by division now. The alpine species have obvious advantages for all kinds of rock gardens, and are, as a rule, easily cultivated and increased by division or by seeds, as well as by cuttings in the spring. Keep the rock garden quite free from weeds by the frequent use of a small hoe or fork. Cut over any overgrown specimens, so that they may not interfere with the development of choicer subjects.

The Kitchen Garden.

Carrots.—The main crop of Carrots should be lifted and stored as soon as possible. A cool, frost-proof shed will suit the purpose well for roots which are required for use during the winter. Later sowings may still be allowed to remain in the open, and the last sowing, which is generally made here in July, may be left in the ground throughout the winter, a covering of rough leaf-soil being applied if sharp frost sets in.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Seakale.—In many districts Seakale will have completed its growth, and where early forcing has to be carried out, a number of plants should have the decaying growth stripped off to allow the crowns to be thoroughly ripened. On the first appearance of frost, throw out these roots, and let them remain on the surface for a time, as crowns which have been exposed to frost will force more readily than those that have not. For general forcing purposes the end of the month will be quite soon enough to make a start.

Chicory.—A few roots of this useful salad may now be lifted and prepared for forcing. Cut the foliage over near the crown, and arrange the roots in large pots or boxes. These may be placed in a Mushroom shed or any convenient place where they can be kept perfectly dark, and where a moderate heat can be maintained. Very little water will be required at the outset.

Lettuces.—Young plants growing outside should now be carefully lifted and planted in small pits or cold frames. It is important to remember that these must have ample ventilation at all times, but not subjected to over-much moisture. If the lights were tilted up back and front, a constant circulation could be maintained.

Mustard and Cress.—To keep up a constant supply, all sowings from this date should be made under glass. For the purpose it is only necessary to use light and very shallow boxes. Sowings, of course, should be made to meet the demands of the establishment.

The Flower Garden.

Pæonies.—Where, from exhaustion or other causes, these plants require to be moved, no time ought to be lost in getting to work, as it should be remembered that they start into growth quite early in the spring. If a border is to be devoted to them, the ground must be deeply trenched,

adding some well-decayed manure as the work proceeds. The moving of the plants should be carried out with the utmost care, as there are perhaps very few plants that resent interference at the roots more than Pæonies.

Delphiniums.—Like the foregoing, where these have to be moved there is no better time to do this than the present, although it must be admitted they are not so impatient in this respect as Pæonies. Delphiniums are, perhaps, more largely grown to-day than they were, and with the many fine varieties now to select from, they will amply repay any little extra care and attention. Recently I saw some large informal beds planted by a stream, and the effect was very striking indeed. The earlier flower-spikes had been cut over, and in the first week of September they were still in bloom.

Begonias.—Tuberous-rooted Begonias should be lifted before they have been actually cut down by frost, and dried off gradually by placing them in an open shed. Allow them to remain there until the foliage falls off, when they should be packed in sand and stored in some frostproof building. Be careful to keep each variety by itself; otherwise great confusion will result in the spring.

Wallflowers.—As soon as the summer bedding plants are cleared, these may be planted in beds or borders, as even planted alone they make quite a good spring display. A very simple and inexpensive arrangement is to plant Narcissus Poeticus ornatus among some dark-flowered Wallflowers. This makes a particularly striking spring display.

Plants Under Glass.

Liliums.—Many of the Liliums, chiefly of the Harrisii type, come to hand about this period, and no time should be lost in having them potted up on their arrival. A suitable compost for these is some good loam, leaf-mould and sand. Place the bulbs well down in the pots to enable them to be top-dressed later. Plunge them in a frame, and if the soil was sufficiently moist when potted, no water should be required until they have made some growth.

Gladioli.—The early flowering varieties, so useful for pot culture in the North, such as Blushing Bride, Peach Blossom and Fire King, should now be potted up into 5-inch or 6-inch pots, using a compost of loam, leaf-soil and a little well-rotted manure. After potting, stand them in a frame that is frostproof, and apply no water until they have made a little growth. On no account attempt to force them, which in most cases would end in failure; they must be allowed to come on naturally.

Bouvardias.—Most of these will now be growing freely and showing the flower-buds. At this stage they will be greatly benefited by an occasional application of manure-water. This, of course, must be given with caution. Be careful not to put too many stakes to the plants, which would not only damage the roots, but also render them unsightly.

Hardy Fruit.

Gooseberries.—Where the bushes have been infested with insect pests, they should be sprayed with one or other of the many insecticides now on the market. Do this as soon as the leaves have fallen. Clear away all loose soil and leaves from round the stem, which is sure to contain hosts of insects, and give the ground a good dusting of hot lime; and no harm will result from dusting the bushes as well.

Fruit Under Glass.

Peaches.—The foliage on most of the earlier varieties will now be ripening, but all attempts at stripping the trees of foliage prematurely should be avoided. Unfortunately, Peach houses, and even vineries, have to be utilised for housing Chrysanthemums and other plants, and, to enable these to get sufficient light, the trees are very often shorn of their leaves before they are ripe. Boards must be placed on the borders to stand pots on, and on dull and wet days it may be necessary to turn on a little fire-heat to dry up the moisture. In such cases the ventilators must be kept open to prevent, in the first instance, any undue excitement of the Peach buds, and also to prevent mildew attacking the plants.

JOHN HIGGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

THE ROCK GARDEN IN LATE SEPTEMBER.

ALTHOUGH late September is not exactly the period when one would expect to find many plants flowering in the rock garden, it is a time when too often this home of alpine and other dwarf vegetation is quite destitute of blossom. This bareness could, to some extent, be overcome were a little forethought exercised at planting-time, as there are quite a number of plants which, although perhaps not strictly natives of mountainous regions, may, nevertheless, be used in the rock garden, and which will give us flowers at this late date.

The following list, compiled while looking through the rock garden at Kew a few days ago, may prove useful to those who desire flowers at so late a season: *Erigeron mucronatus*, low and spreading, with flowers resembling those of field Daisy; *Colchicum cilicicum*, rosy purple; *C. speciosum*, larger, much the same colour; *Convolvulus mauritanicus*, trailing, with deep lavender blue flowers; *Sedum spectabile*, rose-coloured blooms, planted high up on rocks to render it dwarf; *Centaurea montana*, deep blue, 1 foot high; *Senecio Saxifraga*, low trailing, Campanula-like habit, with numerous, small, bright yellow, star-shaped blossoms; *Campanula portenschlagiana*, second display of deep blue flowers; and *Hypericum olympicum*, a trailing St. John's Wort with slightly glaucous foliage and large, bright yellow blossoms, the long filaments of which make a striking central boss.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THE fortnightly meeting of the society held on September 22 was in the nature of a novelty. Owing to the military having commandeered the society's hall at Vincent Square, the Council at the last moment was compelled to make arrangements for the exhibition at the Great Central Hall, Westminster, of which only the lower regions were available. Amid these new surroundings quite a creditable exhibition was brought together, and in conjunction with the annual display of vegetables excited much interest. The holding of an exhibition of fruits, flowers and vegetables in a cellar presented these things in an entirely new light—some, indeed, in little light at all—and while the conditions did not savour of the ideal, and it was impossible to decide as to the colours of certain flowers, both Fellows and exhibitors alike owe the Council not a little thanks for, in the circumstances, providing an exhibition at all.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. C. T. Druery, E. A. Bowles, J. T. Bennett-Poë, J. Green, G. Reuthe, J. F. McLeod, A. Turner, J. W. Moorman, J. Jennings, W. Howe, F. W. Harvey, J. Dickson, H. J. Jones, C. Dixon, W. Bain, C. E. Pearson, W. P. Thomson, E. H. Jenkins, G. Paul and W. H. Morter.

Mr. L. R. Russell, Richmond, displayed an excellent table of stove and greenhouse plants, such fine-leaved subjects as *Dracenas*, *Marantas*, *Caladiums* and *Crotons* playing a prominent part. *Dracena Victoriana* in well-furnished, well-coloured examples were very good, as were also *Alocasias*, *Acalypha hispida* and others.

Mr. C. Engelmann, Saffron Walden, arranged very good groups of Perpetual-flowering *Carnations* *Carola*, *Pioneer*, *Scarlet Carola*, *Gorgeous*, *Circe* (a fancy), *Sunstar* (yellow), *Marmion* and *Variegated Carola*. *White Wonder* and *White Enchantress* were also shown.

Messrs. H. B. May and Sons, Edmonton, showed a miscellaneous group of greenhouse flowering plants and Ferns centred by a well-grown, well-flowered group of *Bouvardias*, of which *Maiden's Blush*, *Dazzler* and *candidissima* were the chief. *Princess of Wales* and *Priory Beauty* were very fine among the blush pink flowered sorts.

Messrs. W. and J. Brown, Stamford and Peterborough, displayed excellent *Roses*, of which *Duchess of Wellington*, *Lady Hillingdon*, Mrs. H. Stevens (white), *La Tosca*, *Rayon d'Or* and *General Macarthur* were a few. These were set in vases and stands, and with masses of *Jessie* made a very showy exhibit.

Messrs. B. R. Cant and Sons, Colchester, also showed an excellent group of *Roses*, the stands of *Irish Elegance*, *Rayon d'Or*, *Lady Hillingdon*, *Gottfried Keller*, *General*

Macarthur, *Louise Catherine Breshan*, *Juliet* and *Mme. Abel Chatenay* being very fine. *Sunburst*, too, was also of high merit.

Mr. J. B. Riding, Chingford, Essex, filled a table with an admirable lot of *Dahlias*, comprising *Cactus*, *Collarette*, fancy, single and decorative sorts. *Ideal* (crimson and white), *V. de Schildt* (pink and white), *Baron Rothschild* and *General de Sonis* (scarlet) were among the best of the *Collarette* section. *Pink Gem*, *Loveliness* and *Carrie* were good among decorative sorts. *H. Witte* is a very fine pure white.

Miss C. M. Dixon, Edenbridge, showed *Michaelmas Daisies* and early flowering *Chrysanthemums* in variety. *Carrie* and *Perle Chatillonnaise* among the latter were very good.

Mr. G. Reuthe, Keston, Kent, displayed *Michaelmas Daisies*, *Colchicums*, *Desfontainia spinosa*, *Saxifraga mandschuriensis*, *Stokesia cyanea*, *Lobelia Queen Victoria* and *Phygellus capensis*.

Messrs. H. J. Jones, Lewisham, showed an excellent lot of *Michaelmas Daisies*, of which *multiflora* (white), *vimineus* (lovely pink), *ericoides* *Perfection* (white), Mrs. Frank Penn (rose), *ericoides* *Delight* and *vimineus* *Golden Rain* were the most charming.

Mr. Ernest Ballard, Colwall, near Malvern, showed many fine seedling *Michaelmas Daisies*, of which *Lady Lloyd* (magenta pink), *Edith Goodwin* (fine blue), *Cloudy Blue* (mauve blue), *Nancy Ballard* (rose), *Jupiter* (pale lavender), *Pleiades* (double white) and *Mira* were some of the best in a really choice lot.

Messrs. J. Carter and Co., Raynes Park, showed a fine bank of *Cactus Dahlias*, nicely arranged with sprays of *Asparagus*. *Pæony*-flowered varieties, with *Pompon*, single and decorative sorts, also added variety and beauty to this excellent group of plants.

Messrs. W. Wells and Co., Merstham, showed *Antirrhinum Nelrose* and *Carnation Champion* in fine condition.

Messrs. Carter Page and Co., London Wall, E.C., displayed a double table of *Dahlias*, of which the *Cactus* and *Collarette* sorts were the chief. *Leitstein* (crimson and white), *Prince John* (scarlet and white), *Inchcape* (dark maroon and white), *Grand Papa Charmet* (bright red and cream) and *Negreo* (maroon and white) were among the best.

Messrs. Joseph Cheal and Sons had an excellent exhibit of cut shrubs with *Dahlias*, the former including *Buddleia amplissima*, a great variety of *Ceanothus* and the white-flowered *Baccharis halimifolia*. *Tamarix hispida æstivalis* was also very fine.

Mr. W. Wells, jun., Merstham, showed some admirable groups of *Phloxes*, of which *Lady Satanella* (fiery red), *America* (pink), *Goliath* (reddish scarlet), *Arthur Ranee* (pink and white), *Africa* (carmine red), *Le Mahdi* and *Mme. A. Buchner* (white) were all good.

Messrs. T. S. Ware, Limited, Feltham, showed *Cactus* and other *Dahlias*, with *Aster Amellus Arethusa*, a very charming plant.

Mr. Amos Perry, Enfield, displayed *Aster Amellus* in variety, *Lilium Biondii*, *Liatris pycnostachya*, *Kniphofias*, *Salvia uliginosa* (fine blue), *Kniphofia Macowanii*, *Colchicum speciosum magnificum* (a fine red), *Senecio pulcher*, *Salvia Griegii* (rich scarlet) and *Pentstemon isophyllus* (rich orange scarlet) in an excellent group.

Mr. J. T. West, Brentwood, showed *Dahlias* of many sections, *Pompons*, singles, *Cactus*, *Pæony* and *Collarette*, all in great variety.

Messrs. Stuart Low and Co., Enfield, contributed a nice lot of *Statice imbricata*, *Chironia ixifera* and some excellent pots of *Nerine Fothergillii*, with *Ferns* and other plants.

FRUIT AND VEGETABLE COMMITTEE.

Present: A. H. Pearson, Esq. (chairman), and Messrs. Joseph Cheal, W. J. Jeffries, Owen Thomas, F. Perkins, W. Bates, H. J. Wright, W. Pope, A. Bullock, P. D. Tuckett, A. R. Allan, William Poupart, J. Davies, Jesse Willard, A. Grubb and E. Beckett.

The most important item before this committee was the gold medal collection of fruits from Mr. J. C. Allgrove, Middle Green, Langley, Slough, and apart from the intrinsic merits of the fruits, the exhibit was of interest in that it connects the old with the new. For many years Mr. Allgrove has managed for Messrs. Veitch the fruit tree department at Slough, which has now passed into his hands. Hence, in the future as in the past, there will be a continuance of those high-class fruits for which for years Messrs. Veitch have been so famous. The exhibit comprised 136 dishes, Apples, Pears, Plums, Figs, Nuts and ornamental Crabs being included. A feature of the group was a number of 2 feet high two year old trees of the new culinary Apple *Rev. W. Wilks*, some of which, lifted from the open and planted in 6-inch pots, were very attractive. One tree alone carried four handsome fruits, a veritable load for a plant of such tender age. The single fruits of the variety in boxes were of huge size, and in many instances also finely coloured. Needless to say, the whole of the fruits were of the finest description, and, occupying a full table length, were a great attraction. Of dessert Apples, Cox's Orange Pippin, American Mother, James Grieve, Rival, Wealthy, Ribston Pippin, Charles Ross, Lord Hindlip and a very fine dish of the new *St. Everard* were on view, among many; while of cooking sorts *Newton Wonder*, *Peasgood's Nonsuch*, *Bramley's Seedling*, *Warner's King*, *Lane's Prince Albert*, *Blenheim Orange* and *Annie Elizabeth* were those which appealed most strongly. Pears, too, were well represented, *Doyenné du Comice*, *Souvenir du Congrès*, *Durondeau*, *Marguerite Marillat*, *Beurré Hardy*, *Louise Bonne* of Jersey, with *Pitmaston Duchess*, being the finer of these. Of *Beurré de Mortillet* there was a grand dish, one giant fruit turning the scale at 27oz. Plums were seen in *Coe's Violet*, *Golden Drop* and *Grand Duke*. While the fruits were of the

highest excellence throughout, they were also admirably displayed, the exhibit meriting the high award granted.

A capital exhibit of high-class fruits, packed for market, was shown in boxes by the Guildford Fruit Farm Company, Guildford. These were contained in the bushel Federated Standard fruit boxes, and averaged 38lb. to 42lb. of fruits. Some twenty-two boxes were exhibited in four varieties, viz., Cox's Orange, Allington Pippin, Newton Wonder and Lane's Prince Albert, a primary object being that of demonstrating the superiority of British-grown fruits when carefully graded and rightly packed.

From Messrs. Dickson and Robinson, Manchester, came a magnificent exhibit of *Onion Premier*, some eighty giant bulbs in superb condition being attractively shown. For size, solidity and rotundity it is hardly possible to conceive anything finer, while the uniform character of the bulbs suggested that all might have come from a single mould. Surely no better evidence of high-class cultivation in this prized and valuable article of food could be desired. An interesting item in the exhibit was a three-podded bunch of the Chinese Runner Bean (*Vigna sinensis*), each of the roundish pods of which exceeded 30in. in length. They were of an exceedingly flexible character.

A miscellaneous exhibit of vegetables came from David Vigo, Esq., Ducketts, Essex, and received a silver Banksian medal.

ORCHID COMMITTEE.

Present: J. Gurney Fowler, Esq. (chairman), Sir Harry J. Veitch, and Messrs. J. O'Brien, F. J. Hanbury, F. Sander, W. Cobb, R. G. Thwaites, J. Charlesworth, T. Armstrong, W. H. Hatcher, C. H. Curtis, A. Dye, E. H. Davidson, S. W. Flory, Gurney Wilson, W. Wotton and J. Wilson Potter.

In a compact group Messrs. Stuart Low and Co., Bush Hill Park, displayed *Cattleya hardyana alba*, *Brasso-Cattleya Maroniae*, *Lælia crispa*, *Cattleya gaskelliana alba*, *C. g. Milady* and the richly coloured *Lælio-Cattleya luminosa*.

Messrs. Charlesworth and Co., Hayward's Heath, had choice plants of *Cattleya labiata Arestor*, *C. Antiope* (deep crimson with sulphur yellow sepals), *Habenaria Susiana* (white), *Paphinia cristata*, *Odontodia Brewii* (very dark coloured) and some choice *Sophro-Cattleyas*, among others. *Zygocalyx Charlesworthii* was also noted.

In the group from Messrs. Hassall and Co., Southgate, N., *Cattleya Loddigesii alba*, *C. Beatrice* and the heavily fringed *Brasso-Cattleya Maroniae* were some of the choicer things.

Messrs. J. and A. McBean, Cooksbridge, showed nicely flowered examples of *Cattleya Harrisonii alba*, *C. Prince Edward*, *Odontodia Bradshawiae* and *Peristeria elata* in a compact little lot.

From Mr. H. T. Pitt, Rosslyn, Stamford Hill, came *Cattleyas*, *Cypripediums* and *Odontoglossums*, with examples of *Dendrobium Phalaenopsis* in variety.

Mr. R. G. Thwaites, Streatham, showed *Miltonias*, *Lælias* and *Odontodas* in some variety.

Messrs. Sander and Sons, St. Albans, had the white *Cattleya Mulleri*, some choice *Odontoglossums* and *Odontodas*, the pretty white-flowered *Oncidium incurvum*, *Cypripedium Franconia superba*, together with *Cattleya Iris*, *C. Adula* var. *Exquisita* and *C. Maronii*. The old and useful *Odontoglossum grande* was well shown.

EXHIBITION OF VEGETABLES.

The annual exhibition of vegetables, held on the 22nd ult. in conjunction with the fortnightly meeting, must be considered a distinct success, both from the quality and quantity of the exhibits. In every class there was considerable competition, and in not a few instances keenness also. In Class 1, for the best twelve kinds, distinct, the Hon. Vicary Gibbs, Elstree, Herts (gardener, Mr. E. Beckett), was in the place of honour with an admirable group, showing in his masterly style *Ailsa Craig Onion*, *Sutton's Prize-taker Bean*, *Tender* and *True Parsnip* (the roots being clean and fully 3 feet long), *Sutton's Perfection Tomato*, *Perfection Brussels Sprouts* and *Windsor Castle Potato* as his best dishes, the whole bedded and garnished with *Parsley*. Mr. T. Jones, Ruabon, was second, having excellent dishes of *International Leek* and *Ailsa Craig Onion* in a well-grown lot. The premier award in this class was the Sutton Challenge Cup, value £21, and £10 in money; second prize, £5. We believe the challenge cup was awarded to the second prize group, since an exhibitor may only win the cup once in three years.

For a collection of nine distinct kinds, Lord North, Wroxton Abbey, Oxon, took the first prize and silver cup for a superb collection of *Runner Bean Sutton's Scarlet*, *Dwarf Gem Brussels Sprouts*, *Best of All Tomato*, *Veitch's Autumn Giant Cauliflower* and *Sutton's Dover Castle Potato*. Second, the Rev. J. McMurdie, Woburn Park, Weybridge, who showed excellent *Beet*, *Wordsley Pride Potato*, *Autumn Giant Cauliflower*, *Celery* and *Pea Autocrat*. There were five collections staged.

For a collection of six distinct kinds, the Rev. J. Davies, Crowlee Vicarage, Worcester, was in the leading place against three competitors with a collection bordering on perfection. His *Invincible Carrots* were worthy of the name, clean, large and of the finest description. *Tender* and *True Parsnips*, *Lyon Leek*, *Premier Onion* and *Money-maker Tomato* (a grand dish) were other important dishes in a good all-round lot. Mr. W. Keep, Reading, was second.

For a collection of twelve distinct varieties of Potatoes, Mr. A. G. Gentle, gardener to Mrs. E. H. Denison, Little Gaddesden, Berkhamsted, was first with a magnificent lot, having *Snowball*, *Royalty*, *Long Keeping*, *Goldfinder*, *Purple Emperor*, *King Edward VII.*, *Windsor Castle*, *Mr. Bresse*, *Herd Laddie*, *Reid's Seedling* and *Excelsior*. Mr. G. Thorn, Willesborough, Ashford, was second. There were four competitors.

THE GARDEN.

No. 2238.—Vol. LXXVIII.

OCTOBER 10, 1914.

NOTES OF THE WEEK.

Why we Should Plant Roses.—Following our usual custom at the commencement of the Rose planting season, we are devoting this issue to articles on our national flower. With the shadow of a great European war hanging over us, we feel how necessary it is to urge upon our readers the desirability of taking an even greater interest in their gardens than they have done in the past. There can be no more peaceful refuge from the horrible stories inseparably connected with war than a well-designed garden, and few flowers are capable of giving so much real enjoyment over so long a period as the modern varieties of the Rose. Nurserymen have during the past year spent large sums in raising stocks of Roses for planting during this autumn and winter, and we feel it our duty at the present moment to urge upon our readers the necessity of taking long views. We are all hoping that the war may be over before the spring, and, unless Roses are planted now, the garden will suffer when Peace is declared. By freely planting now our readers will achieve a three-fold purpose: (1) Relief from the horrors of the war, (2) an improved garden when the present strife is over, and (3) the providing of work for members of a most deserving industry.

Digging Vacant Ground.—Now that the ground is cleared of most of the summer crops, the plot should first be cleared of weeds and rubbish, and, if the soil permits, manure wheeled on and digging proceeded with. There are many who object to this autumn digging, and, where the soil is of a light nature, there may be something to be said for their objection. Where, however, the soil is inclined to be the least heavy, it is just as well to have it turned up as early as possible, so that it may be exposed to the frost. In most well-regulated gardens a certain amount of trenching is done each year. This should also be proceeded with at once.

A Pretty Flower-Bed.—Where what used to be known to all visitors and inhabitants of New Brighton as "Ham and Egg Terrace," there is now a nice green lawn which is relieved by some well-thought-out beds in summer. One which was very pleasing this year consisted of small dwarf standards of a red and white double Fuchsia, which, an under-gardener told us, was called

Eckford, with an undergrowth of a free-flowering Viola somewhat after the style of Kitty Bell. The bed is an oblong, and to relieve the flat look which might be caused if the little standards were all the same height, three in the central line were taller than the others. We did not take any measurements at the time, but from memory we would put the majority down as about two and a-half feet high and the taller ones twelve inches more.

Rose William Allen Richardson.—Among those Roses that may fairly be classed as old varieties, it would be difficult to find one that is a more general favourite than this Noisette. Introduced as long ago as 1878, its deep orange

find a place in all gardens, however small. The annual varieties are very useful, although not to the extent of *S. latifolia*. If required for winter decoration in a dry state, the sprays should be cut when the flowers are at their best, and hung upside down in a dry place.

Sweet Lavender.—There seems to be an increased demand for this aromatic plant with its agreeable fragrance; indeed, many Lavender hedges seen lately seemed particularly effective. To increase the stock a batch of cuttings may now be inserted in cold frames. Although they appear to root somewhat slowly, these cuttings will make nice flowering plants by next season. Rosemary may be treated in exactly the same way.

A Good Autumn Rose.

Although the Hybrid Tea Rose Betty is useless for exhibition purposes, it is a charming variety in the garden. This autumn we have been particularly charmed with its long, conical blooms, and at the time of writing (the last day of September) it is still giving us sheaves of its delightful flowers. In colour these are coppery rose, shaded yellow, and possess the additional advantage of being fragrant. Its habit is vigorous and erect, resembling Mme. Abel Chatenay in this respect, and it is possible that the older variety may have been one of the parents of Betty. So far as our experience goes, the Rose under notice is not subject to mildew or other diseases. It was raised by Messrs. A. Dickson and Sons, and sent out in 1905.

The Conservatory in October.

Let the conservatory be kept as clean and attractive as

possible by the introduction of fresh batches of plants, such as early flowering Chrysanthemums grown in small pots for this purpose. *Salvia splendens* in pots is flowering freely in the open, and should be placed in the conservatory as it becomes necessary. Plants of *Lilium speciosum* which have been grown under cool conditions will also prove useful at this season. Cannas which have been grown in pots may be retained in the conservatory for some time longer. Their foliage is very ornamental, and if the old flowers are picked off, the foliage will lend a pleasing effect to the surroundings. All these plants will benefit by a little artificial manure, and for this purpose guano is one of the best.

The Great Sea Lavender.—*Statice latifolia* and its kindred varieties are among some of our best autumn-flowering perennials, and their value for decorative purposes in the fresh and in the dried state is not sufficiently known. They are of easy cultivation, thriving in almost any kind of soil or position, and should therefore

A LARGE STANDARD OF ROSE WILLIAM ALLEN RICHARDSON.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Clematis Spooneri.—This novelty was introduced by Mr. Wilson, the celebrated Chinese explorer, from whom we received seeds in 1911. It is undoubtedly by far the finest of all the early flowering Clematises, and superior in every way to any other species that flowers in the spring. *C. Spooneri* is a strong-growing species, suitable for covering a house, rough fence, or other structure. The plant is perfectly hardy, and after being planted in a cold, bleak position, flowered well the following season. It bears a profusion of

manure—sheep, cow, horse, not much chicken—1lb. of charcoal in powdered form, and two large spoonfuls of Clay's Fertilizer early in the spring and again when in bloom. It is remarkable what good effects result from using Clay's Fertilizer for other small flowers. I may add, in conclusion, I never let my Roses want for water. Within view of here is St. Paul's Cathedral, and I often think how very odd was the advice given to me when I purchased my first Rose tree. A gardener said it would be useless to try to grow Roses in this locality!—G. R. BUTTON, 4, Worsley Road, Hampstead Heath.

Mixed Arrangement of Hardy Flowers.—Now that we are all thinking about arrangements for another year, I would like to put forward a

A WEEPING STANDARD ROSE GROWING IN A GARDEN AT HAMPSTEAD HEATH.

pure white flowers, which are $2\frac{1}{2}$ inches across, perfectly round and of great thickness. They appear in May and last for several weeks. When better known this species will be a welcome change from the ordinary spring-flowering Clematises.—M. NICHOLLS, *The Gardens, St. Clere, Kemsing, near Sevenoaks, Kent.*

Fruits of Double-Flowered Peach.—I was not aware—nor, I think, are most people—that the fruit of the double-flowered Peach, *Prunus persica flore pleno*, is good to eat. My tree has never given its attention to fruit at all before, but this year it had three. They were nearly as large as, say, a Waterloo, and though not luscious or highly flavoured, they were quite good enough for dessert on Michaelmas Day. Can anyone tell me whether the bright green Pippin-like fruit of *Pyrus japonica* is edible? Mr. Weathers says not; but has anyone tried?—G. E. JEANS, *Shorwell Vicarage, Isle of Wight.* [The fruits of *Pyrus japonica* are not fit to eat in a raw state. They make excellent jelly, though some object to the flavour, and one or two may be added to Apple tarts if desired. They are certainly wholesome.—ED.]

A Good Weeping Standard Rose.—The head of the Rose illustrated on this page measures 9 feet across and the plant is 8 feet high. It was purchased from Messrs. Cutbush and Sons of Highgate, and has been brought to its present condition by following instructions given in *THE GARDEN*. Its food consists of

plea for mixed flowers. For a long time we have been massing and grouping *ad nauseam*, and it would be a change to have a few examples of a less severe colour style. I had several during the past season, and they have proved quite satisfactory. Especially valuable, I am sure, would this style be for isolated beds or small borders, and for small gardens where variety is very important. All kinds of flowers, annuals, perennials, hardy and tender, may be used. One little bed which has been extremely pretty was planted with tuberous Begonias, yellow and salmon pink in equal numbers, with clear blue Lobelia intermixed and a narrow band of variegated Ice Plant round all. This would have been still prettier with a few Snapdragons of a proper colour intermixed. Another scheme was composed of a mixture of *Dactylis elegantissima*, *Veronica Andersonii* variegata, red Begonias and *Nepeta Mussinii* kept regularly reduced to proper proportions, with Lobelia and variegated Anthemis as a border. The effect of this was very pleasing, the Begonia giving it the touch that saved it from insipidity. A long border partially grouped with such things as Gazania, Heliotrope, Lobel's Catchfly, double Godetia Schaminii, &c., had running through them single pink and mauve Asters, tall yellow Snapdragons, standard red Fuchsias and *Veronica Andersonii*. I have adopted the same principle to some extent in mixed borders, such plants as Francoa, *Gilia coronopifolia*, Gladioli, Antirrhinums, Lilliums, Montbretias, Lobelias of

the cardinalis type, Sweet Williams, Celcias, Phloxes and Japanese Anemones, with a lot of dwarfer-growing material, being suitable. Quite a number of plants having flowers of the same shade may be associated, with the best results, the point aimed at being dissimilarity of form rather than of colour.—R. P. BROTHERSTON.

When to Plant Tulips.—I fully agree with Mr. John Dunn that Darwin and other late-flowering Tulips should be planted in September. Our practice here at Lowdham is to begin planting late Tulips as soon as the Daffodils are all in, which is generally about the first week in September. I have never seen any ill results from early planting, but, on the other hand, have often noticed that the late-planted bulbs were inferior to the early planted ones, both as regards foliage and size of blooms. I very much doubt if "fire" is caused by early planting, or, rather, that early planted bulbs are more subject to it than those put in later. "Fire" is, I think, just a matter of climatic conditions. With us it always seems to follow sharp frosts or hail, followed by rain. The frost or hail alone will not do the damage, but, when followed by warm rain and close weather, "fire" often spreads very rapidly and does much damage. May-flowering Tulips nearly all start to grow in the dry state sooner than do the bedding varieties, which looks as if they needed planting earlier. Then, again, the soil is in so much better condition in September than it is in November. In the case of a strong, retentive soil such as we have here, it is often impossible to plant bulbs as they should be planted when the work is deferred until November. One of the largest of the Dutch growers told me some years ago that he always planted his Darwins before his bedding varieties. This did not influence me, for I had previously planted early, but it was a comfort to know that I was backed in my opinion by a good man. It is quite possible that bedding Tulips might with advantage be planted earlier than they generally are, but every gardener knows the difficulty of getting his beds and borders ready for them. At the present time many beds and borders are as gay as ever they were in July or August; and who could have the heart to destroy the present display for the sake of a possible improvement in the Tulips next spring?—J. DUNCAN PEARSON, *The Nurseries, Lowdham, Notts.*

—The letter of "Observer (Weybridge)" on this subject in *THE GARDEN* of September 26, page 471, reminds me of an unusual experience I had in Tulip culture a good many years ago. The stock had all been planted—so I thought—during October or November. To my consternation, however, when sorting out the newly arrived seeds early the following February, I came upon a parcel of early Tulip Keizerskroon, or, as I now prefer to designate it, Grand Duke. I decided, to give them a chance, and planted them alongside another batch of the same variety which had been planted for cutting purposes, and closely watched their development. They appeared above the ground about a week later than the earlier-planted batch, and the blooms opened correspondingly late, but beyond this there was no visible difference between the two lots. I only record this experience to show that one may take considerable liberties with the Tulip.—CHARLES COMFORT. [It would be interesting to know how the late planted bulbs behaved the following year.—ED.]

PREPARING LAND FOR NEW ROSE BEDS.

MANY readers who have followed our advice in past years and have thoroughly prepared the soil of their gardens before planting Roses have been loud in their praises of the hints thus afforded; but as *THE GARDEN* is constantly enlisting new readers, it has been thought advisable to repeat such information as will be helpful just now when, as we hope, many are contemplating new plantings of our national flower. The delightful freedom of flowering of our modern Roses when planted in well-prepared soil gives to them undoubted pre-eminence among the denizens of our gardens. We may rightly value the thousand-and-one other subjects, but where can we obtain such a constant blooming from the end of May until the frosts of November excepting from the lovely Hybrid Tea, Tea, Monthly and Polyantha Roses?

As I have already hinted, to keep up this continuity of blooming the plants must be kept ever growing. I have seen beds of Tea Roses that after their first blow in June have been in an almost stationary condition owing to the want of proper preparation of the soil. If there is a good depth for the roots of the Roses to obtain fresh food, their very natural propensity to produce new shoots will be considerably assisted. Therefore I would urge upon all readers who contemplate planting Roses this autumn to start as early as possible and trench the soil.

Unsuitable Soil.—It is of little assistance to tell readers what soil is best for Roses, for as a rule they have to make the best of what is available. Many possess the idea that Roses must have clay, but while granting that clay is desirable, it is not indispensable. To anyone possessing a light soil that is inclined to be sandy, with a gravel subsoil, I would say, see that the Roses have a depth of 3 feet of the best soil available, removing the gravel if necessary to secure this. Into the lower 2 feet incorporate plenty of cow and pig manure. This is worth some amount of trouble to procure, and is far better than strawy stable manure that one must too frequently have resort to. If it is practicable to import a cartload or two of heavier soil, do so by all means.

Heavy Soil.—On the other hand, those possessing a heavy subsoil of clay should take care that this is well broken up by adding burnt earth, which may often be procured from a brickfield, or some road grit, other than from tarred roads, or, failing this, some agricultural chalk. There must be no water-logged soil if our Roses are to do well, but, so long as water will pass away freely, the subsoil may be of a very heavy nature, and the Roses revel in it. I have the true Tea Roses, such as Mrs. Myles Kennedy and Lady Roberts, growing in soil the lower stratum of which would make good bricks, and all that I have added has been burnt earth and some pond mud. Ordinary town ashes are a good material to improve a heavy subsoil, but we may make our own burnt earth by means of a sack or two of coal dust, some faggots and some clay soil to burn.

Trenching the Beds or Borders is carried out as follows: Mark out a section of 3 feet in width at one end of the bed. Remove the top 12 inches of soil to where the work will finish.

Now thoroughly break up the next 18 inches or 24 inches of soil and incorporate the ingredients named. I also advise giving 6oz. of basic slag to a square yard. Having done this, start another section and dig the top foot of soil on to section No. 1. If it is turf being dealt with, a thin layer of the grass should be skimmed off and burnt, or else put into the bottom of the trench with the grass downwards. If

Isolated Positions are to be planted with one or more Roses, these also should be prepared on the same lines, and for ramblers on arches and pillars or climbers against walls or fences I would advise holes being dug 3 feet wide each way and the same in depth. I once knew a gardener who had a millionaire employer. He thought he would go one better than other people, and so for every pillar Rose he planted he had a cartload of new compost put into big holes. But what a grand result followed! I was astounded to find the plants at the top of 10-feet to 12-feet Larch poles in a very short time, certainly not more than two years. They were not only at the top, because this can be accomplished in one

ROSES THAT LAST WELL.

IT is natural that the national flower should be the most popular of all the many flowers largely grown in this country, for the same varieties that are grown massed in beds in the large Rose gardens of the wealthy may also be grown in the mixed beds of the suburban garden or the plot of ground cultivated by the cottager. To the extraordinary development and improvement in the habit and colour of the Rose must be given much of the credit for its popularity; but there are yet other achievements to be attained, and the keen lover of the Rose is on the look-out for them and welcomes them with open arms, quickly making room for them in his already well-filled garden; and just as the single Roses were welcomed yesterday, so to-day and to-morrow the Roses which last both on the plant and in a cut state take the premier position. The Roses of gorgeous colours are, alas! too often those which one must be an early riser to see in all their beauty, for the

THE BOWL OF ROSE DOLLY VARDEN SHOWN BY MESSRS. GEORGE PAUL AND SONS AT THE NATIONAL ROSE SOCIETY'S SHOW LAST JULY, WHEN IT RECEIVED AN AWARD OF MERIT. IT IS A HYBRID RUGOSA, AND THE SEMI-DOUBLE FLOWERS ARE GLOWING APRICOT SALMON PINK IN COLOUR.

year, but they had thickened out so wonderfully. By taking these precautions and seeing to it that the land is prepared about three weeks before planting, success is assured to the veriest tyro, providing always good sound, well-rooted plants are set out. I would also advise a stock of bone flour to be in readiness, so that each Rose may receive a handful at the time of planting; but see to it when planting that the manure is kept away from the roots. The bone-flour is scattered on the soil when the roots are covered and just before the final layer is added. W EASLEY

"thin" Roses so lovely in the bud are too soon full blown and too quickly gone. The long-lasting Roses are comparatively few in number, but they embrace practically all colours and shades, and afford a wealth of choice even to the most discriminate of choosers.

Foremost in the reds one must place *Château de Clos Vougeot*, darkest of all Roses, and a treat in store for those who have not grown it. Of rather horizontal growth, it should be pruned to an eye pointing upwards and inwards to correct this peculiar weakness. It will hang for days

on the plant, and revels in the hottest sun. There were few visitors to the shows this summer who did not notice how George Dickson lasted, even on the hottest days. Leslie Holland, Lieutenant Chaure, with Laurent Carle, are also good keepers; so, too, are the older but fine Roses Hugh Dickson and General Macarthur. Mme. Abel Chatenay revives when placed in water, even after it has wilted. Willowmere, Mme. Segond Weber, Lady Alice Stanley, Mrs. Alford, Mrs. John Laing, Mme. Maurice de Luze and Jonkheer J. L. Mock are prominent among salmons and pinks as Roses with thick, leathery, long-lasting petals. In pale pinks there are Prince de Bulgarie and its improvement, Mme. Rostand; Ophelia and Pharisæer. It seems only the other day that good yellow Roses were scarce; indeed, the ideal yellow Hybrid Tea did not exist. Thanks

Goodwin, and Louise C. Breslau, which is similar but of a deeper apricot shade; also M. Paul Lédé and its new sport Climbing Paul Lédé.

Among new Roses, the variety which has impressed me as a lasting Rose to an unusual degree is Mrs. Charles Russell, an American introduction. A Rose which so well withstands the sun of the United States may be expected to fall into the category which we have under consideration. The way this variety remained fresh all through the terrific heat which prevailed at the time of the Holland House Show was quite instructive. Flowers which were cut on the Monday lasted until the close of the show on Thursday evening. This Rose is of a pretty, non-clashing shade of old rose pink, has a good perfume, and is of vigorous, good habit. Altogether the study of Roses is perpetually interesting, but not least instructive

but can never be overtaken. But in the effort to reach it we have many beautiful experiences which those who are content with mediocrity can never know, so that no one has yet produced the ideal Rose of our imaginations, yet hybridists are yearly adding to our gardens Roses which, in one respect or another, do approach the ideal. It is hard to imagine a Rose of more perfect form than British Queen, of more glowing colour than Mme. Edouard Herriot, or of more delicious scent than H. E. Richardson, and all of these are of very recent introduction.

Possibly during the last ten years, which have seen the wonderful advance of the Hybrid Teas, the qualities of form, colour and floriferousness have been more highly esteemed than that of fragrance. But if this has been so, I think the tide has begun to turn. A special cup was offered last June at the Holland House Show for the Rose having the "true Old Damask scent," and at the National Rose Society's Show the judges of seedling Roses were instructed that "some importance is now attached to scent, which, though not always attainable, gives a Rose an added charm." This may, perhaps, be considered rather a mild way of describing what to many is the *sine qua non* of a good Rose; but it is, I believe, the first time that judges have been specially asked to consider fragrance as one of the "points" of a new Rose. Mrs. Bertram Walker, a variety of fine form and colour, had also the charm of fragrance, and if it proves to be of good hardy habit, will well deserve the gold medal which it was awarded.

Mrs. George Norwood, a beautifully shaped Rose of a clear soft pink, has a delicious scent, and should certainly be tried by anyone wanting a good new Rose. This Rose competed for the "Clay" Cup which was offered at Holland House for the variety not yet in commerce having in the most marked degree the real Damask Rose scent. Some seven or eight varieties were shown, and the cup was awarded to a Rose of Messrs. William Paul and Sons' appropriately called Queen of Fragrance. If there is anything in a name, it should do well. It was a large, rather flat, pink flower, flushed in the centre with bright blush pink, and, I imagine, like Mrs. George Norwood, belonged to the Hybrid Tea class. Though bright in colour and very fragrant, it was not nearly such a beautifully shaped Rose as Mrs. George Norwood. Messrs. Alexander Dickson and Sons showed a Rose called Mrs. Bryce Allen, which, though neither bright in colour nor good in shape, had a wonderful fragrance, and from it the diligent hybridist may evolve more beautiful and equally sweet-scented progeny. These varieties will, I hope, be offered for sale this autumn; but, naturally, they will still be expensive, and in the nature of experiments. I will now mention a few well-tried, though comparatively recent introductions. In looking through a list of Roses of the last five years, I have noted the following varieties as being specially fragrant:

Andre Gamon (1909, H.T.).—A fairly vigorous variety of deep carmine pink, good shape and real Rose scent.

Lady Alice Stanley (1909).—Very vigorous. If grown in too strong a soil, the flowers are apt to come coarse; but in a light soil and not overtaken they are well shaped, of very attractive colouring, coral rose on the outside of the petals and pale pink on the inside. The very pronounced scent is a mixture of Tea and Hybrid Perpetual. **WHITE LADY**

(To be continued.)

A BOWL OF ROSE CLIMBING SUNBURST, A GOOD "LASTING" VARIETY.

to Rose raisers, the position is now quite otherwise, and among many fine yellows Sunburst stands out as the best Rose to last in this or any other colour. The first crop of flowers of this variety come pale, almost white, but I have known blooms used in church vases to remain fresh for a week. There are not many Roses that would last in this way. The new climbing sport, Climbing Sunburst, is, of course, equally durable.

The white Roses are not numerous. Frau Karl Druschki is, of course, one of the best; but the new scented Druschki, Mrs. Andrew Carnegie, lasts equally well, and Molly Sharman Crawford in a lesser degree. Among Roses of other colours which outlast other sorts there is ample choice—Marquise de Sinety and the sort which may one day supplant it because of its superior habit, viz., Mme. Lutand; Juliet; that grand bedding coppery orange variety A. R.

is the extra amount of pleasure one may get by planting the Roses which last. **LADYBIRD.**

SOME RECENTLY INTRODUCED SWEET-SCENTED ROSES.

THEORETICALLY, all Roses should be sweet-scented, as they should all be of good form, perpetual habit, pure colour and perfect hardiness. But in a plant which has shown itself capable of such infinite variety that "custom can never stale" its charm, it would seem almost too much to expect that any one kind should combine in itself in a marked degree all these desirable qualities. The ideal in Roses, as in other matters, is not easily come by. Like the will-o'-the-wisp, it is always luring us on,

SOME OF THE NEWER ROSES SUITABLE FOR EXHIBITION.

FIND as each autumn arrives that amateurs are more desirous than ever of planting Roses that possess beautiful form and also substance, so that if necessary they can exhibit the blooms. And one is not at all surprised at this. Far too many novelties of the present day possess but three qualifications. They are most lovely in colour, with delightful buds, and make vigorous growth, but the full-blown flowers are little more than single. We are then bombarded with enquiries for full Roses—"a good full Rose"—and it is with the object of introducing such to the reader that this article is written. As the older varieties are well known, it will only be necessary for me to name the newer kinds, and I will do so briefly and in alphabetical order. There are several others I could name, but I prefer to give them another season's trial before pronouncing on their merits.

Alexander Hill Gray (T.), although not large, is, nevertheless, of such fine shape that it should find a place in every collection. I have been very pleased with it this year, and it throws up fine, strong basal growths crowned with grand blooms of a deep lemon colour.

Alice Lemon (H.T.) is a blush white variety of exquisite form and fulness. It is of American origin.

Annie Crawford (H.P.).—Those who saw this Rose at Bath when it obtained the National Rose Society's gold medal will not soon forget it. The boxful was one of the features of this fine show. The blooms are of wondrous size and splendid form; it is probably the largest Hybrid Perpetual grown. Maiden plants will grow to a height of 6 feet to 8 feet. If it is a free bloomer as a cut-back it will be most valuable. It struck me as being a superior Mrs. John Laing.

Augustus Hartmann (H.T.).—This has been exhibited so grandly by its raisers, Messrs. B. R. Cant and Sons, that I have no doubt as to its merits when in the hands of the skilled grower. The colour, geranium red, seems to be an advance on George C. Waud.

Aviateur Michel Mahieu (H.T.).—Decidedly good, coral red, with vivid centre. It has fine long buds, very distinct in colour, deepening as the season advances.

Candeur Lyonnaise.—Really an improved Frau Karl Druschki with a lemon tinge, and a much fuller flower. Perhaps in general appearance it is too much like its parent, and it will be difficult for judges to distinguish one from the other.

Colleen (H.T.).—As I saw it at Portadown this Rose was really wonderful. Its fine guard petals were a feature. The colour is brilliant rose pink.

Comte G. de Rochemur (H.T.).—A very neat flower of brilliant scarlet red. A good front-row flower and very free.

Coronation (H.P.).—An extraordinarily vigorous grower and a grand flower of the colour of Her

Majesty, with a more majestic form. Perhaps not free blooming enough for a garden Rose, but this I cannot say definitely until after another year's trial.

Countess of Clanwilliam (H.T.).—Delicate peach, flamed cherry red. I thought this the best novelty I had seen when visiting Belmont last year, and I would advise all exhibitors to get it.

Countess of Shaftesbury (H.T.).—Exquisitely lovely in the bud and when half open. Rather thin when fully out, but, if well disbudded, most useful for show; it is one of the best of garden Roses. Colour, bright carmine pink.

C. W. Cowan (H.T.).—A very fine colour, midway between Marquise Litta and George C. Waud. There being so few rich red Roses among the Hybrid Teas, this should be very welcome.

ROSE MRS. CHARLES RUSSELL, A NEW ROSE PINK VARIETY THAT LASTS FRESH A LONG TIME WHEN CUT.

Dr. Nicolas Welter (H.T.).—Rosy salmon, with vivid centre. Fine long, egg-shaped flower and a glorious garden Rose.

Duchess of Normandy (H.T.).—A sport of Dean Hole, and its counterpart in every way save colour, which is salmon flesh paling to cream.

Duchess of Sutherland (H.T.).—Like a glorified Captain Christy, with a more shapely flower. Superb in form, not very free in the autumn, and a terror for mildew.

Edgar M. Burnett (H.T.).—An improved La France. This variety will be as great a favourite as Lady Alice Stanley.

General-Superior A. Janssen (H.T.).—Glowing carmine. Excellent grower. Much deeper than Mrs. W. J. Grant. Will become a general favourite.

Geoffrey Henslow (H.T.).—Another Rose of the colour of George C. Waud. Apparently a better grower and altogether most promising.

George Dickson (H.T.).—The "best dark Rose in the world," as I heard it described, and well worthy to bear such an honoured name. If it only carried its flowers erect and did not produce so many split blooms and were freer in blooming in the autumn, with less mildew, I should value it more; but no exhibitor can afford to be without it, and perhaps we have yet to learn how to treat it best.

H. V. Machin (H.T.).—Scarlet crimson. A magnificent bloom, one that we shall all want.

Jewel (H.T.).—One of the purest whites and quite large. The flowers are like big Water Lilies. Lovely in the half-open stage.

Killarney Brilliant (H.T.) is sure to be good. The colour is almost crimson.

King George V. (H.T.).—Almost a Hybrid Perpetual. Not very free flowering, but a splendid bloom and very valuable to the exhibitor. Colour, violet crimson.

Mabel Drew (H.T.).—One of the best of the Newtownards Roses, which is saying a good deal. A very refined flower, almost Tea-like in this respect. Colour, pale creamy yellow.

Mme. C. Chambard (H.T.).—Rosy flesh, from Prince de Bulgarie. Fine form and most promising.

Majestic (H.T.).—Colour, carmine rose, of grand form and fulness.

Marcella (H.T.).—Salmon flesh, very full. Good.

Margaret (H.T.).—Scarcely a novelty now, but should be grown by everyone. A fine deep flower of soft pink colour.

Marquise de Ganay (H.T.).—If well disbudded, blooms may be had of splendid size and very perfect form. Although a pink, it is distinct. A most prodigious bloomer.

Mayflower (H.T.).—Decidedly good, reminding one in colour of old Devoniensis, only of much better form and fulness.

Mrs. Amy Hammond (H.T.).—May be grown to an immense size. It is so very distinct that all must have it. Colour, amber and cream.

Mrs. Andrew Carnegie (H.T.).—A much overrated Rose. I have not seen a good flower all the season. It grows well, and perhaps some may show it well if it is shaded and papered up, but it is

a Rose I would not care to recommend while we have others better.

Mrs. Charles Russell (H.T.).—Very fine and with such lasting properties. The petals are almost wax-like in texture. Colour, rosy carmine.

Mrs. E. Alford (H.T.).—A Rose better under glass than outside, although at times it is good. It is a very bad one for mildew. Colour, silvery pink.

Mrs. George Shawyer (H.T.).—Of superb form and clear rose pink colour. Should be well sprayed to prevent mildew. Early in the summer it is grand.

Mrs. James Lynas (H.T.).—A grand Rose as seen at Belmont. I hope it will turn out as well in England. Colour, pearly pink, shaded peach.

Mrs. Muir Mackean (H.T.).—A distinct Rose and of fine form. Very useful. Colour, carmine crimson.

Mrs. R. D. McClure (H.T.).—Probably the best of last season's novelties. Like a very warm-coloured Lady Ashtown.

Mrs. Wallace H. Rowe (H.T.).—Very fine, of rather dwarf growth, reminding one of Papa Lambert in form and colour.

Nerissa (H.T.).—Good. Almost a dwarf Mme. Jules Gravereaux. Opens badly in wet weather.

Ophelia (H.T.).—A magnificent Rose, and at times quite good enough for a front-row flower. Colour, salmon flesh, shaded orange.

Souv. de M. Floquet (H.T.).—Another of the George C. Waud colour, rather less full, but more globular. It has been very fine with me.

COLOURED PLATE.

PLATE 1502.

THREE GOOD GARDEN ROSES.

THE three Roses shown in the accompanying coloured plate were purposely selected as three excellent and comparatively new Roses for garden decoration. Neither of them is a really good exhibition sort, but all are excellent for bedding and for cutting. Taking them in order of seniority, we must first deal with General McArthur. This was raised in America and first put into commerce in 1905. It must have been

with this, as we have never had them behave in this way.

Next must come Lady Hillingdon, raised by Messrs. Lowe and Shawyer, and sent out in 1910. We feel that we owe an apology to this charming Rose. For the first two years that we saw it and grew it, we were not greatly enamoured with its behaviour. Its flowers hung their heads too much and did not seem to come a good colour. This last two seasons, however, it has improved very considerably in both respects, and may be fairly regarded as one of the best yellow bedding Roses that we have. It is a Tea Rose and very charming when cut, and in the half-opened stage is ideal for button-holes. It has a moderately vigorous habit

A BEAUTIFUL EFFECT OBTAINED BY USING RAMBLER AND DWARF ROSES IN CONJUNCTION.

St. Helena (H.T.).—At times too much like Joseph Hill. It may, perhaps, be of better habit, but is evidently a seedling of that grand sort, and we have now enough of that type.

Sunburst (H.T.).—Magnificent and quite good enough for a show box, whether of a pale colour, as it frequently appears, or its true deep cadmium yellow.

There are undoubtedly some other good Roses of recent introduction that will prove excellent for exhibition, and it would be interesting if those who have grown them would send their experiences to the Editor. Roses behave so differently in different localities that too much cannot be known about them, especially these newer varieties.

DANECROFT.

very soon after that date when our attention was drawn to it in Messrs. Stuart Low and Co.'s nursery by Mr. L. J. Cook, who then predicted a brilliant future for it. That his high opinion of it was justified, time has proved. As we write, in the closing days of September, a bed of this deliciously fragrant Rose, edged with the white Polyantha Katherine Zeimet, is one of the most brilliant and pleasing features in our garden. This Hybrid Tea Rose has a vigorous, branching habit, is seldom attacked by mildew, flowers freely from June until well into October, and the blooms are as fragrant as the Roses of our forefathers. In a few gardens we have seen the blooms take on rather a blue tint during the very hottest days of July, but imagine that the soil must have something to do

and is not so much addicted to black spot and mildew as many other sorts.

The third Rose in the plate, Louise Catherine Breslau, we owe to the skill of M. Pernet-Ducher. It is classed by the National Rose Society as an Austrian hybrid, but we hope the race will soon be known as Pernet Roses. As it was only sent out two years ago, we cannot say a great deal about it at present, except to predict that it will become, in a few years' time, one of the best-known garden varieties. It is really an improved Arthur R. Goodwin, a Rose of which we have always held a very high opinion, but which is scarcely vigorous enough in many gardens. We have seen Louise Catherine Breslau growing in several nurseries last year and this, and intend to find room

for a few bushes this autumn. It appears to have a good constitution, and those who have grown it are not at all backward in singing its praises. Messrs. H. Merryweather and Sons of Southwell, Notts, to whom we are indebted for the flowers from which the coloured plate was prepared, consider it one of the best garden Roses of its colour—and they are good judges.

**POLYANTHA
ROSES IN THE
GARDEN.**

WITH the advent of the Baby Ramblers, the class of Dwarf Polyanthas forms a charming addition to our bedding Roses. These so-called Baby Ramblers are, of course, not ramblers at all, but little dwarf bushes from 1 foot to 2 feet in height, and nearly always in flower. Only in the shape and the large trusses of flower and, to some extent, in their foliage do they resemble the ramblers. As far back as 1879 a separate class existed for Polyantha Roses, or, as the National Rose Society prefers to call them, so as to distinguish them from the Multifloras, the Polyantha Pompons. This was at a time previous to the great new class of Hybrid Teas and during the pre-eminence of the Hybrid Perpetuals and pure Teas. Among the then small collection of these miniature-flowered kinds there were several, mostly with large bunches of flowers, used for edging and small beds, some, like *Perle d'Or* and *Cecile Brunner*, Tea-like in form, and others, such as *White Pet* and *Mignonette*, favouring the Multiflora and the Sempervirens hybrids in their shape of flower and leaf. All of them were small flowered, and of dwarf and perpetual habit.

Some of the best of these are still grown, and are yet extensively used as a finish to beds of large-flowered kinds. Of these the following are to be recommended: *Anna de Montravel* (1879), white, very dwarf, beautiful form. *Cecile Brunner* (pale pink) and *Perle d'Or* (salmon yellow), both with large, bold bunches of flowers; a fine match in form and habit, and persisting until

October. *Mignonette* and *Gloire des Polyanthas*, pink and rose pink, alike in habit, with trusses of cup-shaped, semi-double flowers. *White Pet*, like a dwarf *Félicité Perpétue*. All of the foregoing make fine edging or bedding kinds. These were followed by the two Lameschs—*Eugénie Lamesch*,

since the introduction of the Baby Ramblers that attention has been directed afresh to this class. Following closely upon *Crimson Rambler*, *Dorothy Perkins* and other new climbers, they have fitted in so well with the new scheme of Rose gardening as to obtain a well-deserved

A CHARMING GROUPING OF ROSES AND DELPHINIUMS IN A GARDEN AT SURBITON HILL. PLANTING TIME WILL SOON BE HERE.

with the scent of *Parma Violets* and valuable for its colour, clear yellow, edged mauve; and *Léonie Lamesch*, most distinct in its shades of terracotta red and orange, but rather taller than the others of this section. These earlier varieties still have a certain vogue, but it is

popularity. The first of them, *Mme. N. Levavasseur* (Baby Rambler), proved dull in colour and in dry seasons sometimes failed to continue its crops of flower, but it was quickly followed by better and brighter kinds. *Maman Levavasseur* (Baby Dorothy), a dwarf, very free pink;

Katherine Zeimet, perhaps the freest and best white; Phyllis and Mrs. Cutbush, pinks; and, finally, Jessie and Orleans, reds, are among the latest additions. Another good white is Jeanne d'Arc, not only good in itself, but a first-rate companion to Mrs. Cutbush and Jessie, the three going remarkably well together. Jessie is probably the most perpetual and continuously blooming Rose we have. Beginning in late June, it persists until the November or December frosts, retaining its dwarf habit and yielding innumerable crops of crimson scarlet flowers. Mrs. Cutbush as a clear pink and Orleans as a rosy scarlet are in the same way, but slightly taller. All these varieties have shiny, clean foliage, and Mrs. Cutbush and Orleans have flower-stalks sufficiently long to enable them to be cut for table decoration. These Pompon Roses should be planted in beds closely together, about 15 inches by 12 inches apart. They replace with advantage the Geraniums and other plants in summer bedding, and in the Rose garden they add a finish and an elegance to the Teas and Hybrid Teas, and may be planted as an edging to these larger-flowered kinds or separately in a bed, the flatness of such beds being with advantage broken up by the insertion of a few half-standards of the same kinds on 2 feet to 2½ feet stems. These half-standards are particularly attractive and floriferous. Also the value of such kinds as Jessie and Orleans as pot plants has already been proved. They are always in bloom and easily grown, and they mingle, too, so well with the Ramblers in pots which are so much used in house and greenhouse decoration.

Finally, a word must be said as to the other and newer varieties. Erna Teschendorff is a deep rich crimson sport from Mme. N. Levavasseur, but possessing its faults as well as its merits. Aennchen Müller has immense trusses of flowers, but is subject to mildew. Varieties like Kleiner Alfred, Miese and Cyclope are delightful in colouring, but do not grow well, and so are useless for massing. A really good yellow has not yet been obtained, though, after Eugénie Lamesch, perhaps George Elger may be cited as the most suitable for massing. This last is distinctly promising, but is closer to the Tea section than to the Baby Ramblers. Aschenbrödel is a most delicate pink in colouring and is distinct. The variety Queen of the Musks, with almost evergreen foliage and mildew-proof, is somewhat lacking in brightness, but probably will be the progenitor of future kinds. It is most profuse and autumnal. Röd-hätte, a hybrid between Jessie and Hybrid Tea Liberty, is intermediate between its two parents. It has bold bunches of light red flowers, a clean, bright green foliage, and is never out of bloom. Yvonne Lornage, a vivid coppery terra-cotta and red, promises well and is most distinct, and Maman Turbat and Jenny Soupert may prove useful additions to the pinks. Some advance has

been made with the singles, and of these Papa Hemeray, growing from 1 foot to 18 inches, with large bunches of single flowers, crimson in colour, is distinctly good. Altogether a very pretty class, and one likely to be developed in the near future.

G. LAING PAUL.

THE BEST AUTUMN-FLOWERING ROSES.

THE wonderful strides that have been made in the improvement of Roses during the last ten or fifteen years are never at any other time brought quite so vividly to our notice as

ROSE FLORENCE FORRESTER, A NEW WHITE HYBRID TEA RAISED BY MESSRS. S. MCGREDY AND SON.

during the waning days of autumn. Instead of the straggling bushes, with their few badly formed flowers, that were the rule rather than the exception, we now have the Rose garden in September, and often well into October, almost as brilliant and certainly quite as interesting as in the more genial days of June and July. The present year has been an exceptionally good one for Roses, especially where the beds were mulched early with short manure to preserve the natural moisture of the soil, and I do not ever remember seeing such a beautiful autumn display of good blooms as there is just now. In some respects these autumn Roses are preferable to those of summer; they may not be quite so large, but the cooler weather enables the exquisite colour of some to be better

revealed, while the blooms last in good condition for a much longer period, whether cut or left on the bushes. This lasting character is recognised by the National Rose Society, who held a two days' autumn show last year for the first time.

Now that there are so many good autumn-flowering Roses, it is not without some hesitation that one ventures to compile a list of the best. Differences of opinion there will always be, and it is necessary to remember that a Rose which does well in one garden will not always give good results in another. Most of the varieties named here I have had under observation for three years, some considerably longer, and their inclusion is not based on their behaviour in one garden, but in many, as well as in some of the largest Rose nurseries in many parts of the country. Crimson and scarlet shades: *General McArthur, Richmond, Liberty, *Ecarlate, *Grüss an Teplitz, Hugh Dickson, J. B. Clark, Florence Haswell Veitch and *Château de Clos Vougeot. Pink shades: *Caroline Testout, *Lady Ashtown, *Lady Alice Stanley, Mme. Segond Weber, Mrs. E. J. Holland, Gustav Grunerwald, *Miss Cynthia Forde, Königin Carola, La Tosca and *Zephyrine Drouhin. Yellow, orange and buff shades: *Arthur R. Goodwin, *Duchess of Wellington, Rayon d'Or, Marquise de Sinety, *Mme. Ravary, Lady Hillingdon, *Amateur Teyssier and Crépuscule. Shaded salmon, fawn or apricot: *Prince de Bulgarie, *Pharisäer, *Mme. Léon Pain, *Mme. Abel Chatenay, Earl of Warwick, Betty, *Lady Pirrie and Frau Lilla Rautenstrauch. Cream and white: *Entente Cordiale (Ducher), Molly Sharman Crawford, *James Coey, Mrs. Herbert Stevens, *Frau Karl Druschki and Mrs. David McKee. Nita Weldon should come here, but the flowers are not erect enough for bedding. In addition to the varieties already named, I would include *George C. Waud (vermilion, suffused orange) and *Frances Charteris Seton, usually described as rose pink, although it is scarcely what one usually associates with that colour. It is an excellent Rose, and very fragrant. Among the whites one would like to include White Killarney, were it not such a martyr to mildew.

Of Dwarf Polyantha Roses there are several good varieties for the autumn, the best of all, in my opinion, being *Jessie, which commences to produce its unfading clusters of bright scarlet crimson flowers early in July, and never halts until the frosts of October put it out of court. Orleans, with bright pink flowers, is very charming in the autumn; during the hot days of summer its blossoms get badly scorched. Aennchen Müller, with its clusters of rather large pink flowers, which have curiously but not unpleasantly twisted petals; and Katherine Zeimet (white) must also be named here. For the benefit of those who will shortly be planting, I have marked with an asterisk what I consider the best two dozen bush Roses for autumn flowering. It would be interesting and

A ROSE ARCH PHOTOGRAPHED SHORTLY AFTER ERECTION AND JUST AS THE ROSES HAD BEEN PLANTED.

useful if readers would send the Editor other lists.

For rambling Roses that flower in autumn we must forsake the wichuraianas and turn to the Teas, Noisettes, climbing forms of Hybrid Teas, or Bourbon hybrids. Longworth Rambler (light crimson), Ards Rover (crimson), Gloire de Dijon (buff), Climbing Caroline Testout, Climbing Mrs. W. J. Grant, Armosa (pink), Bouton d'Or (usually referred to as an improved Gloire de Dijon) and Danæ (creamy yellow) are about the best. William Allen Richardson, the well-known rambling Noisette, is this year flowering well for the second time in many places, but its behaviour as an autumn-flowering Rose is rather erratic. Gustave Regis, too, is flowering well now, but, though suitable for pillars, is scarcely strong enough for arches or pergolas. It is one of the best button-hole Roses we have, its long, pointed buds of nankeen yellow being always acceptable. H.

ROSES ON ARCHES, PERGOLAS AND PILLARS.

SINCE the advent of Crimson Rambler and its retinue of wichuraiana hybrids, a good deal of interest has been taken in Rambler Roses, and it is difficult now to find a garden of any dimensions without an arch or post supporting one or more of the many beautiful varieties obtainable. This is undoubtedly a step in the right direction. These Rambler Roses, judiciously used, are capable of creating very beautiful effects in the garden, as will be seen in the illustration on page 494, where ramblers are used in conjunction with bush varieties. There we see part of a lofty pergola gracefully clothed with free-flowering ramblers, the beauty and interest of which cannot be denied.

Unfortunately, most of these Roses have only one flowering season; but a few hybridists, notably the Rev. J. H. Pemberton, are devoting their attentions to the creation of a perpetual-flowering race, and already there are several varieties obtainable which flower freely in autumn as well as in the warmer days of summer.

But even though we only get three or four weeks of blossom from the wichuraiana hybrids, they are so beautiful as to justify us in planting them freely. At one time we used to find trellis and arches clothed with Ivy, Virginian Creeper, or other more or less uninteresting plants, but now their places have been taken by the Roses. Apart from the wichuraiana and multiflora hybrids, however, we must not overlook the large-flowered rambling varieties—sports in most instances of well-known Hybrid Teas or Hybrid Perpetuals. Thus we have rambling forms of Mrs. W. J. Grant, Liberty, Lady Ashtown and Sunburst, Roses the value of which can scarcely be over-estimated, especially where good blooms are required for cutting. We must remember that these strong-growing forms of our

favourite bush Roses give almost, if not quite, as good blooms as the bush plants, and, owing to the greater length of stem, in much larger quantities. In addition to these there is yet another type of Rambler Rose with large flowers, good examples of which are Mme. Alfred Carrière, white, and Longworth Rambler, bright cherry red. These are exceedingly vigorous and flower from June until well into October; hence their value in the garden must not be overlooked.

When we come to Roses for pillars or posts 5 feet or 6 feet high, we have quite a number of excellent semi-rambling varieties to select from. Grüss an Teplitz, Gustave Regis, Zephyrine Drouhin, Irish Elegance and Hugh Dickson are all good Roses that do best when allowed to extend to large bushes, and each will easily clothe a pillar of the height named. They are all ideal for cutting, and it would be difficult to select a more charming Rose for a button-hole than the half-opened bloom of Gustave Regis.

The mention of pillar Roses brings to mind two excellent varieties that have had this name applied to them in rather a misleading way. I refer to Paul's Carmine Pillar and American Pillar. It is perfectly true that both do make excellent pillars, but their vigour is such that they are more at home over a tall arch, trellis or pergola, where their bushy growths can develop fully. In the Rose Number of THE GARDEN last year

the illustration at the top of this page was used as an example of a good rustic arch, the posts being placed 4 feet 6 inches apart each way, and the height over all 8 feet. The photograph from which that illustration was prepared was taken at the end of March, 1912, directly after it had been constructed and the Roses planted. The other illustration on this page is from a photograph of the same arch, but from a different standpoint, taken in July this year, i.e., a little over two years after the Roses were planted. Four varieties were put in, one at each post, viz., American Pillar, François Foucard, Shower of Gold and Mme. Alfred Carrière. The variety seen so prominently in the second illustration is American Pillar, which has clothed the whole of one side of the arch and smothered François Foucard, as well as taking unto itself the whole of the roof. On the other side Mme. Alfred Carrière has done well, and Shower of Gold is struggling for space. Many of the rods of American Pillar were at pruning-time 14 feet long, and were shortened back to about eleven feet. During the whole of July this Rose was a picture to behold, its large trusses of rose pink single flowers, with their white centres, lasting in good condition for over a month. It is a Rambler Rose that ought to be in every garden in the United Kingdom. Paul's Carmine Pillar is also a single-flowered Rose, and one of the earliest to open its blooms. If grown as a pillar, it ought to have a support at least 10 feet high, and it will grow much taller than that. At Kew it is allowed to ramble at will over an old evergreen, I believe a Holly, and the background of dark green foliage mirrors into greater relief the vivid colour of the Roses. Unfortunately, the blooms are fugacious, but its vigorous habit, freedom of flowering, and the early date at which the blooms open, place it in the category of the indispensables. S. X.

THE SAME ARCH PHOTOGRAPHED A LITTLE OVER TWO YEARS LATER

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Peach Trees in Pots.—The necessary pruning and thinning of these trees should be accomplished at once. Very little water will be needed until the trees are placed in the forcing-house. If red spider has been present on the foliage during recent dry weather, the trees must be thoroughly washed before they are introduced to their winter quarters. In the meantime they should be fully exposed to the weather, but some means must be adopted to keep them from being blown over by rough wind.

Vines.—Young Vines which were planted in April should still be growing freely, and must receive a liberal supply of clear water at the roots. Lateral growths may be cut back to within one eye of the main stem in order to secure the full benefit of the sun. Ventilate freely during the day, shutting the house early in the afternoon; but damping of the floors or wall will not be necessary now.

Midseason Vines from which the Grapes have been cut may now be half-pruned in order to plump up the buds near the base of the shoots. Examine the borders and, if necessary, give a good soaking of clear, soft water. The ventilators may be left open day and night.

Plants Under Glass.

Chrysanthemums.—No time should be lost in removing the plants from the open air to a well-ventilated structure, where they should be fully exposed to the light. Do not place the plants too closely together, as this will have a detrimental effect on the foliage. The latest batch of plants may still be left in the open, but some protection should be at hand in case of frost. If blinds are available, some temporary spars can be placed in position 2 feet above the plants, so that the blinds may not come in contact with the foliage. Some stimulant will be necessary, but must be applied in moderation, or more harm than good may result.

Euphorbia jacquiniæflora.—This is one of the handsomest winter-flowering stove plants, and succeeds well when planted in the warmest end of the stove and trained on the roof. As a pot plant the best results are obtained by striking three or four cuttings in a small pot in the spring, and potting them on undisturbed as it becomes necessary. By this method the plants do not require stopping, and the shoots will, consequently, be much stronger. Very careful watering is necessary, and, when the flower-buds are formed, the plants will benefit by applications of weak manure-water.

Camellias.—Disbudding should be carefully performed before they are too far advanced, leaving one bud on each shoot where the plants are in robust health. Syringe twice daily with soft water when the weather is favourable. If necessary, a top-dressing of turfy loam and peat may be applied after the removal of the old surface soil, and this must be made quite tight by ramming. Manure-water may be applied with advantage. The soil must never be permitted to become too dry, or the buds will drop in consequence.

Azaleas which have been grown in the open during the summer should now be removed to a cool house where air can be freely admitted. Syringe with clear water daily, and if thrips are present on the foliage, the house should be carefully fumigated once or twice to make quite certain of their destruction.

The Flower Garden.

Agapanthus and other specimen plants in tubs should be placed under cover, with as little delay as possible. Large plants of Ivy-leaved Geraniums may be placed in some well-ventilated structure where they will receive as much light as possible during the dark days of winter.

Lobelia Cuttings.—It is not too late to part and make cuttings of stock plants which may have been cut over for the purpose. The small cuttings are preferable, as they will stand the winter much better than old plants. A close, cold pit is all that is necessary, providing sufficient silver sand is used.

Begonias may be lifted as soon as the foliage has died down, and the tubers placed in shallow boxes. When quite dry they may be stored in a dry, frost-proof room until the spring.

The Hardy Fruit Garden.

Planting.—The earlier this work is taken in hand the better, especially if the trees have been grown at home for a season with the intention of filling vacant spaces, as in this case it is unnecessary to wait until the leaves drop, providing the roots are moistened before lifting. But if the trees have to be brought from a distance, it is not advisable to lift them so soon as to cause the bark to shrivel, or the result will not be satisfactory. Sweet Cherry trees, which lose their leaves early and are among the first to bloom, may be lifted first. When planting fruit trees of any kind, if the same site has to be occupied again, an effort should be made to provide new soil for the purpose, and this may frequently be obtained from some part of the garden where fruit trees have not been grown. This may be enriched with crushed bones, old lime rubble and thoroughly decomposed manure from the farmyard, which should only be applied as a surface-dressing. Drainage is an important matter in heavy soil, and this must be carefully attended to in the first instance. In such soil deep planting must be avoided.

The Kitchen Garden.

Mushrooms.—There need be no difficulty now in providing a supply of Mushrooms throughout the winter if sufficient horse-manure is available to make up the beds. This should be collected daily and placed in an open shed, where it may be turned every second day until it is ready for removal to the Mushroom-house. Place the manure in position and allow it to remain until the temperature of the material rises to 85°. At this stage the manure should be rammed tightly together, and spawning may take place when the temperature has dropped to 80°.

French Beans in Pits.—Young plants in flower should be freely ventilated during mild weather. Give a liberal supply of water at the roots and do all that is possible to promote clean, healthy growth. Another sowing may be made in 7-inch pots, which should be placed in a temperature of 65°. As soon as the plants are well through the surface, they should be placed within 18 inches of the roof glass. Syringe twice daily, and as growth advances give frequent waterings of liquid manure.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Mushrooms.—Beds that were spawned about the beginning of last month should now be producing Mushrooms. Attend carefully to the damping of the paths and walls, and if the surface becomes dry, a slight spraying of tepid water must be given. Some clean straw may be spread over the surface, which will keep the bed in a fairly moist condition. Continue to collect fresh horse-manure for successive beds, spreading it out in a dry, open shed and turning it frequently to prevent heating.

Parsnips.—In lifting and storing root crops it should be remembered that Parsnips keep better in the ground than out of it, so that roots ought only to be taken up when wanted. Should frost be severe, a covering of some strawy manure may be spread over the ground. This will prevent injury to the roots and facilitate the raising of the crop when wanted.

The Flower Garden.

Roses.—Dwarf Roses should be gone over at this season and any unusually long shoots shortened back to at least half their length. If left alone, these strong shoots are frequently broken off entirely at the base by wind. But perhaps the most serious danger resulting from these shoots is their swaying to and fro, thus loosening the plants and breaking off the more tender roots. Where it is intended to make

new plantations next month, the ground should be prepared at once, so that there will be no delay in planting when the Roses arrive.

Sweet Peas.—The sowing of Sweet Peas in the autumn (that is, in pots) has much to commend it. Some years ago we sowed a large batch about the middle of October, and we had the satisfaction of having them still in bloom the following October. Sow five or six seeds in a 6-inch pot, cover with half an inch of soil, and place the pots in a cold frame. When the young growths appear, remove the pots to a cool house and place them on a shelf near the glass. Very little water will be required during the next two months.

Spanish Irises.—It would be difficult to imagine anything more beautiful than a collection of these lovely Orchid-like flowers, which come into bloom about the beginning of June. It would be quite out of place to mention varieties, as they are all more or less beautiful. The bulbs should be planted about four inches deep in loose, sandy soil and the same distance apart.

Plants Under Glass.

Poinsettias.—These fine winter decorative plants, which have been hardening their growths in frames, should now be placed in a warm house where the temperature can be maintained at 60°. Stand them where they can have full exposure to the light, and as the pots will now be well filled with roots, artificial feeding may be given. On no account allow the plants to become dry at the roots.

Malmaison Carnations.—Young layers potted up last month should now be removed from the frames to the Carnation-house. Before doing so, all shading must be washed from the glass and the woodwork inside thoroughly washed down. Where gravel or ashes are used on the stages, they had better be renewed, so that everything is fresh and clean. During the next three months these plants require very little water. Admit air day and night, and in dull and foggy weather only turn on sufficient heat to keep the house dry.

Tuberoses.—The first of these bulbs, chiefly from Africa, arrive about this time, and should be unpacked at once and spread out on shelves, as, owing to the long time they are in transit, they often get heated, which renders them entirely useless. Before potting, it is most important that each bulb be cleaned—that is, all the small bulblets removed—otherwise the result will be a mass of foliage and very poor flower-spikes.

The Hardy Fruit Garden.

Planting Wall Trees.—A start should now be made in preparing the ground where wall trees are to be transplanted, and at the outset it may be said that if this work is done carefully, the trees will suffer very little check. Prepare a trench of sufficient size to suit the particular tree to be moved, and have at hand some chopped turf and old mortar rubble, to be worked in among the roots. Before unfastening the trees from the walls, work the soil from the roots, retaining as large a ball as can be conveniently moved. To remove the tree an ordinary plank or garden mat should be worked under the ball. Avoid deep planting at all costs, and carefully spread out the roots as the work of filling in the trench proceeds. Finish by giving the ball a thorough soaking of water to settle the soil in the trench, and give a slight mulching of manure to encourage root action.

Fruit Under Glass.

Vines.—No time must be lost in pruning those Vines that are intended for early forcing. Unless mealy bug has been present, the rods should not be scraped; this often does a vast amount of harm. Merely rub off the loose bark with the hand, wash down the woodwork, and run a cloth soaked in paraffin over the wires. Remove all loose surface soil and top-dress with some good loam. When the work is completed, keep the house wide open and as cool as possible; indeed, a good sharp frost up to 10° would do no harm. Unless the border is dry, no water should be given until the house has been closed down and growth commences.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

ROSA PERNETIANA: 1838—1914.

EARLY in the reign of Queen Victoria a new Rose named Persian Yellow arrived in England whose manners and colour won the admiration of rosarians of the day. This little visitor was taken everywhere, and in the years that followed was to be found in all parts of the world. Some sixty years after its arrival M. Pernet-Ducher arranged a successful match for this wanderer, from which he gave us Soleil d'Or in 1900. Rather plain of form, the fierce prickles, reddish wood and scented foliage denoted a new break. A few more years passed away in that famous garden not far from the shores of the Mediterranean where Persian Yellow first settled down. A rosarian went on quietly working among his Roses, till once again he startled the Rose world by sending over the Lyon Rose, another member of Persian Yellow's family. No need for me to describe the delight of everyone. That April meeting of the Royal Horticultural Society is still fresh in our minds. Recollect once again those beds at the Franco-British Exhibition of 1908, and how everyone wished to possess this Rose painted with an artist's brush! It was realised that M. Pernet-Ducher had created a new race. Other raisers soon followed. Several have used this blood with success, some in keeping the strain pure, others infusing the Pernetiana colour into the Hybrid Teas. After Soleil d'Or and Lyon Rose we had from several sources Les Rosati, Gottfried Keller, Entente Cordiale and Soleil d'Angers; then Juliet (the pride of an English firm), Louis Barbier (one of the most attractive for pillar work), Johannesfeuer, Parkfeuer, Rodophile Gravereaux and the charming Beauté de Lyon (with huge red thorns and fragrant foliage). These are more or less after the style of Soleil d'Or in habit of growth.

Arthur R. Goodwin, Mme. Ruau, Viscountess Enfield and Rayon d'Or possess the characteristics of the Pernetiana break—scented foliage resembling Pineapple, the reddish wood, fierce prickles, with beauty of form and habit of growth like the Hybrid Teas. At the International Exhibition in London, 1912, a special prize was offered for the best new seedling Rose. This coveted honour was won by M. Pernet-Ducher with Mme. Edouard Herriot. The demand was so great that everyone had to wait a year longer to possess this wonderful Rose, but it can now be obtained from most nurserymen. Its colour is always described differently. Some have it deep terra-cotta or reddish copper; the National Rose Society have it vivid terra-cotta, passing to clear strawberry rose. Can you imagine it? No; but when your plants bloom you will agree with either description. The form, habit and constitution are everything to be desired. Like its ancestors, this Rose is destined to travel into gardens throughout the world.

Louise Catherine Breslau has mildew-proof foliage. Willowmere, named after Admiral Ward's home in America, is an improved Lyon. Cissie Easlea, a saffron yellow fusion from Mme. Melanie Soupert and Rayon d'Or, is very free-blooming. It may interest readers to know that several of the Pernetianas were in bloom until after Christmas, 1913, Cissie Easlea being the best. Before the charm of Mrs. George Beckwith, Rayon d'Or pales. The former is a deeper and more brilliant yellow, combined with handsome foliage and

thorns. We are impatiently waiting for its fair presence in our gardens. Constance Ward, the Constance of the International, is more vigorous and of better habit than Rayon d'Or, blooming freely; a charming shade of old gold. Mme. John Crouch, a sport from Lyon Rose, is an acquisition; and Marie Adélaïde Grande Duchesse de Luxembourg, an attractive shade of orange yellow, is well thought of by our friends across the water. I have only seen it in two gardens. Those who like the various shades of yellow will appreciate it.

Messrs. Alex. Dickson of Newtownards fame, who have utilised the Austrian strain for some years, have some very special and promising varieties of this class. Mr. Hugh Dickson has given us an attractive variety from an Austrian Yellow seedling crossed with Joseph Hill, which he has named Mrs. Hugh Dickson, a rich yellow, tipped rosy pink, suffused with apricot, beautifully formed large blooms; it grows freely. One of his latest is Muriel Dickson, after the colouring of Mrs. A. R. Waddell, with an effective glow in the bloom, very charming. It possesses red thorns, is always in bloom, excellent for bedding, and really a wonderful colour.

Messrs. B. R. Cant have sent us Autumn Tints. It has Pernetiana blood, and also inherits some of Mme. Edouard Herriot's colour. Another acquisition in this class, from Mr. T. W. Piper, we have in F. J. Barry, a pure yellow sport of Arthur R. Goodwin, which it resembles in all but colour.

Sonnenlicht is an interesting variety, very useful for hedges and massing. It is from Mary Fitzwilliam crossed with Harrisonii, and has pure canary yellow, semi-double blooms, with a delightful perfume; free blooming.

Messrs. S. McGredy and Son infused the Pernetiana blood into the Hybrid Teas with excellent results, shown in the gorgeous colours seen in Old Gold, Lady Mary Ward, Mrs. F. W. Vanderbilt and Mrs. C. E. Pearson. We want perpetual climbers in Pernetiana colours after the style of growth of Dorothy Perkins. Who is going to give them to us?

On May 5, 1914, some seventy-six years after Persian Yellow came to England and fourteen years after the creation of a new race, the Council of the National Rose Society of England decided that this race should in future be known as Rosa pernetiana, an honour well earned by the raiser and a happy tribute of the Entente Cordiale existing between this country and France, shown in the welcome given to Their Majesties King George and Queen Mary on their recent visit. Our national flower has always been in Royal favour. A basket of blooms was presented to Queen Mary on Coronation Day, 1911, by the National Rose Society. The beauty of it can be seen in the Rose Annual for 1912. The Gracious Patroness of the National Rose Society, Queen Alexandra, accepted a charming basket of flowers on St. George's Day, when the Pernetianas were again in request for their colour.

And what of M. Pernet-Ducher, the man whose skill has enriched our gardens beyond his own dreams! The gorgeous array of seedlings to come make us realise the wonderful mystery of Nature. What memories in the background of a mind so richly stored! The day Persian Yellow was fertilised, when the results of labour bore fruit, the quiet triumph felt as the slow creation of a new race went on under his hand; The readers of THE GARDEN wish him many happy days among the Roses he loves so well.

A list of Pernetiana Roses is given below—founders of the race, Persian Yellow and Antoine Ducher, their first offspring Soleil d'Or: Arthur R. Goodwin (Pernet-Ducher), Beauté de Lyon (Pernet-Ducher), Cissie Easlea (Pernet-Ducher), Constance Ward (Pernet-Ducher), Deutschland (Kiese), Entente Cordiale (Guillot), Gottfried Keller (Dr. Müller), Juliet (W. Paul), Johannesfeuer (Turke), Lyon Rose (Pernet Ducher), Louis Barbier (Barbier), Louise Catherine Breslau (Pernet-Ducher), Les Rosati (J. Gravereaux), Mrs. George Beckwith (Pernet-Ducher), Mme. Edouard Herriot, Mme. Ruau (J. Gravereaux), Mme. John Crouch (E. Turbat), Marie Adélaïde Grande Duchesse de Luxembourg (Soupert et Notting), Parkfeuer, Rayon d'Or (Pernet - Ducher), Rodophile Gravereaux (Pernet-Ducher), Soleil d'Angers (Ch. Detriche), Viscountess Enfield (Pernet-Ducher) Willowmere (Pernet - Ducher), Muriel Dickson (Hugh Dickson), Autumn Tints (B. R. Cant), F. J. Barry (Piper), and Sonnenlicht (Kiese). It will be interesting to note in which class those Messrs. McGredy have so successfully infused with Pernetiana colourings will be placed in the reclassification now being discussed. E. E. F.

[The foregoing article, by an esteemed lady correspondent, was written before the outbreak of war, but is particularly applicable now that our Forces are fighting side by side with those of our French friends. The husband of our correspondent is with His Majesty's Army, and we feel sure that our readers will join with us in wishing him a safe return.—ED.]

THE EDITOR'S TABLE.

A Good Early Pear.—Messrs. George Bunyard and Co., Royal Nurseries, Maidstone, send fruits of a good early Pear named Michaelmas. This variety was raised in Gravesend from a seed of Winter Nelis, and first introduced by Messrs. Bunyard in 1900. The fruit is rather small, roundish, and greenish yellow in colour, but the flesh is white, sweet, of good flavour and melts very easily. We understand that the trees crop regularly and freely, and this being so, we anticipate that Michaelmas will prove one of the most useful dessert Pears for this season.

A Beautiful Autumn-Flowering Shrub from Cornwall.—Mr. J. E. Sanders, Green Lane Nurseries, Redruth, sends flowering sprays of Escallonia montevidensis. The white blossoms are borne in fairly large terminal panicles, and at a short distance look very much like white Lilac. They have a neat foil of glossy, evergreen foliage. It would be interesting to learn if this charming shrub has proved hardy in more northern parts of the country. Mr. Sanders writes: "I enclose a few sprays of Escallonia montevidensis. I thought it would interest you to know that this is an excellent autumn-flowering species. It has been in flower for nearly two months, and looks promising to remain in flower for at least another month. It also makes a nice specimen. The plant these flowers were cut from is growing in a border, and is 22 feet high and 8 feet through."

Roses from Essex.—Our esteemed Rose contributor, Mr. W. Easlea, sends from his Danecroft Nursery, Eastwood, Essex, some very charming autumn blooms of Rose Mme. Edouard Herriot. The wonderful flame colour is particularly good in these blooms, cut on October 1, while they possess almost as much substance of petal as those that open early in the year. Mr. Easlea,

in writing, states that the plants are as vigorous as those of Caroline Testout. He also sends a specimen of a new Rose of his own raising named Oraoenta. This is a charming shade of shell pink, and the large flower is of excellent, conical form. In addition it emits a delightful and powerful fragrance, so that it should be a great favourite when better known.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

VIOLET-COLOURED VERBENA (M. E. Gladstone).—The one variety most likely to meet your requirements is that known as Lovely Blue, which in one garden of our acquaintance is bedded out in its thousands. Not only is it excellent in colour, but it is also highly fragrant, of good constitution and free in flowering. It was raised, or introduced, we believe, by Messrs. Keynes, Williams and Co., Salisbury, and you might obtain flowers from that firm to give you an idea of its colour. They might also submit flowers of others of a similar hue. Godetias usually come true from seed, and there should be no difficulty whatever in securing the shade you require. Sutton's Double Rose and Satin Rose are in the colour range you name, and these, with others, are offered in the catalogue of Messrs. Sutton and Sons, Reading. Moreover, we saw these varieties, with many others in excellent condition in the seed trial grounds of the firm named, a few weeks since.

PRIMULA PULVERULENTA (Mabel M., Carlisle).—This species is a true perennial and will endure for years. The best effects are, however, secured when the plant is raised periodically from seeds, not quite on a biennial plan, but very near this. The reason is that the seedlings surpass in vigour, stature and freedom of flowering the plants raised by means of division or in other ways, and, if grown in a wet or fully moist position, will attain 4 feet high, flowering in proportion. Moisture, indeed, is essential to its fullest development, while it is one of the finest species of a semi-bog-loving nature that we know. The plant produces seeds in abundance, and these while fresh vegetate freely and quickly. We have seen self-sown seedlings springing up in their hundreds at the base of groups planted near water or in quite moist places. It is natural for the leaves to turn yellow in autumn and for the plant to revert almost to a corm in winter. Such things are, however, influenced by the degree of dryness or wetness about the plants, and also by the mildness or severity of the winter itself.

WATER LILIES IN BASKETS (E. Moon).—These should still be kept in the baskets in which they have been grown during the season. Do not, on any account, disturb them at the roots during the dormant season. See that they are sufficiently low down in the water for

the crowns not to become frozen. Not that this would injure them, but it is expedient not to incur the risk of both expansion and contraction. Guard against any injury by voles (sometimes called water-rats) by placing a ring of galvanised wire around the tank or pond. In the spring—about the end of April—look to their condition, and, if the plants need larger baskets, place them in such. In any case, give them a top-dressing of good loamy soil, leaf-mould and road grit. Press this down firmly, and at the same time see that the rhizomes, if not firmly established, are well secured. Another way of keeping Water Lilies through the winter is to take them out of the water and cover them with leaves, so that they are not frozen. This will give sufficient moisture, as a rule; but should the leaves become dry, give them a good watering. As recommended for plants in water, guard against the vole and also the rat.

TREES AND SHRUBS.

TREATMENT OF TREE LUPINE (Burton).—Your Tree Lupine may be pruned a little now, but spring is a better time. Towards the end of February you may cut the shoots back fairly hard if you so wish, and new branches will be formed towards May; but if you prune severely now and the late autumn proves mild, new shoots may be formed which would be killed in the event of a severe frost being experienced. Nevertheless, it will not hurt to remove a few of the outgrowing branches.

CLIMBERS FOR WALLS (W. M. B.).—The only way in which you can assist Ivy to cling to your walls is to nail strips of wood to them, to which the Ivy can attach itself in its early stages. Of the two, Ampelopsis muralis is hardier than A. Veitchii, though both are hardy enough for most parts of this country. There is also very little to choose between them in the rate of growth. A. Veitchii is, however, the neater plant. Your Fuchsia may be pruned towards the end of winter, say, February. As a rule, Fuchsias are not cut into wood older than one year. That is, the previous year's wood is pruned back to within a few buds of the base.

PROPAGATING SHRUBS (W. S.).—The correct time to propagate Buddleia variabilis veitchiana and Hydrangea paniculata is from June to August, cuttings of soft shoots being used. These are inserted in pots of sandy soil in a close and, for preference, slightly heated propagating-frame. It is possible, however, that if you make cuttings of ripened shoots 9 inches to 12 inches long and insert them outdoors as soon as the leaves fall, they will root during the winter. The cuttings should be inserted in a slanting position in well-drained ground, and it is advisable to place a little sand at the bottom of each trench before the cuttings are inserted. Do not disturb such cuttings for a year. About three inches of each cutting should be left above the ground, the remainder being buried.

TREES FOR PLEACHED WALK (R. E. D.).—The common Lime is one of the best trees to form a pleached walk, and is used more frequently than any other. Even though your position is somewhat exposed, we think you will do better by planting it than by using another tree, for although the Elm could be employed for the same purpose, its roots would impoverish the soil in the vicinity over a greater area than the roots of the Lime. The trees should be planted about ten feet apart, and the front and back growth restricted while the side growth is allowed to develop. Gradually bend the heads across the walk until they meet, and when the top and sides are all clothed with branches, give an annual pruning to prevent overgrowth. The walk may be made any width you desire.

THE GREENHOUSE.

FRUITS OF FICUS REPENS (W. F. Dark).—The fruits of Ficus repens are not usually eaten, and it is doubtful whether they have any food value.

SOIL FOR CYCLAMENS (S. J. C.).—A very suitable compost for potting off young plants is equal parts of loam and good leaf-mould with a liberal sprinkling of silver sand. These should be well mixed together, and if passed through a sieve with a one-third of an inch mesh the operation of potting will be facilitated. A few broken crocks must be put in the bottom of each pot for drainage, and immediately over them a little of the rougher soil that has not passed through the sieve.

HINTS ON AURICULAS (Auricula).—Yes; it is advisable to repot Auriculas annually, and the best time is May or early June. This subject was dealt with fully in our issue of May 9, 1914. A few leaves will decay, even with the most expert growers, but if each plant is losing, say, five or six leaves at this time of the year, something is wrong in the treatment, and it may be, as you suggest, overwatering or the other extreme. It would not be for the want of repotting, as the plants were only recently purchased. If, however, the soil is in a sour condition or the stem at all loose, we should not hesitate to repot even now. Good fibrous loam forms the principal part of Auricula compost, and so far as our experience goes, the colour does not make a lot of, if any, difference. Those potted in a peaty mixture no doubt suffer from drought, and we advise you to leave out the peat when the time arrives to repot. We know it is most difficult to properly water a collection of Auriculas when they are repotted in different soils. The best plan would be to arrange them according to the soil employed; then you can study each group, and would, no doubt, obtain much better results. The mixture you have used should give satisfaction; but Auriculas, like most plants, require attention throughout the year,

especially in regard to watering and ventilation. No coddling is needed, and Auricula culture may be summed up in the word "moderation." At the time of repotting, all offsets with three or four small leaves may be removed, but the usual time is February and August. We referred to this matter in our issue of August 8, 1914, and February 7, 1914, and if these instructions are carried out, there will be few offsets when the plants are repotted. Offsets with no roots can be severed near the main stem, and then treated as cuttings. Three or four are placed around the edge of a 3-inch pot, using the ordinary mixture with a little more sand added. If put in a hand-light and kept closed for a week or two, they will soon make roots, when they should be potted off in single pots. When repotting old plants, the stem must be lowered so that the foliage is near the soil. If the variety is a choice one and it is desired to increase the stock, lower the stem to the offsets, otherwise they can be rubbed off and discarded. We do not know of any chemical that would kill the aphids without injury to the roots. This pest is not so harmful as an amateur would imagine; but if the frame is vaporised occasionally, a large number will be killed. At the time of repotting, Tobacco powder can be sprinkled among them with fatal results. Methylated spirit may also be used, and no harm will be done to the roots or plant.

ROSE GARDEN.

YELLOW ROSES FOR COLD GREENHOUSE (Roach).—We think you will find Melody one of the best to keep its colour, and for a good deep yellow Lady Hillingdon should do well, although, being a Tea, it would require some artificial heat. Herzogin Marie Antoinette has been very good with us. Perhaps it would be best to try this also. Sunburst is very apt to produce pale blooms in the first crop. Rather than add lime to your potting soil, we would suggest some bone-flour at the rate of about two pounds to a bushel of compost.

RAMBLER ROSE DISEASED (A. J. C.).—The Roses are attacked by mildew. Try Seride, which can be obtained from Messrs. Gleeson and Co., 41, High Street, Watford. Clematis montana would answer very well in the position you describe against a south wall. It is probable that you will find Escallonia macrantha the most suitable shrub for your arch. E. langleyensis would grow more rapidly, but it is of looser habit and not so strictly evergreen. It is, however, a very beautiful shrub. Both Escallonias give excellent results in Cornwall.

ZEPHYRINE DROUHIN AS A WALL ROSE (Mrs. Sherrard).—We should not select this beautiful Rose for a house climber. It will, in the course of five or six years, attain a height of 10 feet to 12 feet; but its best position is against a fence or pole, where it can grow to a height of 6 feet to 8 feet, as it is more inclined to become bushy than tall. A good wall Rose would be Dr. Rouges. It is a glorious rich colour, or, if you would like a pale colour, Climbing White Maman Cochet or Climbing K. A. Victoria would be fine. Rather than remove the Rose, why not plant a standard of some good climber close to it, one that would soon cover the vacant space? We would suggest for this purpose Climbing Mrs. W. J. Grant, and most growers can supply such Roses in standard form.

DISEASED ROSE AND CELERY LEAVES (Dr. A. R. W.).—The Rose leaves are attacked by the Rose black spot, and the best treatment is to spray the bushes with Bordeaux mixture from early May onwards at intervals of a fortnight or three weeks. The cause of the spot is a fungus called Actinonema rosæ, and the spray treatment should be combined with the destruction of all the diseased foliage possible. The Celery is attacked by the Celery leaf spot, due to the fungus Septoria Petroselinii Apii, which has become so prevalent during the last few years. It is usually distributed by the seed, and the only thing to do now is to pick off all the affected parts and spray the remainder with Bordeaux mixture. The spraying should be commenced early next season, and every endeavour made to get the seed free from the fungus.

SUBSTITUTE FOR NATURAL MANURE (New Reader).—We quite appreciate your difficulty in obtaining natural manure for your new Rose-beds. In towns, and even in the country, it becomes increasingly difficult each year owing to motors displacing horses to so large an extent. We do not know of any better substitute for adding to the soil when preparing new beds than Wakeley's Hop Manure. We have used it extensively for several years with excellent results. The spent Hops which form its basis add humus to the soil, and this is particularly necessary and valuable. In addition, the Hops have been treated with lasting chemical plant food, so that beneficial results are obtained over a comparatively long period. You will find this manure advertised in our pages, and we advise you, and others similarly situated, to give it a trial.

ROSES OF GOOD SUBSTANCE (A. P. F. G.).—We can quite appreciate your desire to plant Roses of good substance, especially after a season like the present. Unfortunately, a number of Roses are wanting in fulness, and yet in the autumn days they are the most beautiful and open more readily than the double kinds. You will find the following good varieties, and they are all Hybrid Teas, as you desire: Deep red—Florence H. Veitch, Lieutenant Chauré, General Macarthur, George Dickson. Liberty and Chateau de Clos Vougeot; pink—Countess of Shaftesbury, Joseph Hill, Lady Ashtown, Mme. Abel Chatenay, Mme. Segond Weber and Mrs. George Shawyer; cream and white—Mrs. Arthur Munt, Ophelia, Molly Sharman Crawford, British Queen, May-flower and Souvenir du Président; yellow—Le Progrès, Sunburst, Souvenir de G. Prat, Mrs. Aaron Ward, Melody, and Herzogin Marie Antoinette.

THE GARDEN.

No. 2239.—VOL. LXXVIII.

OCTOBER 17, 1914.

NOTES OF THE WEEK.

Our Garden Planning Competition.—It is with pleasure that we announce in this issue the results of our competition for planning and planting the little garden. The selection of the winning designs has involved a considerable amount of labour, and we hope that those published this week will be of assistance to our readers who are contemplating the alteration of their gardens or the planning of new ones. Next week we shall publish more of the prize designs, with explanatory notes and criticisms of their respective features. We feel sure that our readers will agree that the competition has been more than justified by the results achieved.

War Fund Fruit Sale at Covent Garden.—Fruit sales are common enough at Covent Garden, but on Wednesday, October 7, a sale took place the like of which even the oldest salesman had never seen before. A remarkably fine lot of British and foreign fruit had been gathered together—gifts from growers, merchants and private people—and the spacious hall was crowded to its utmost capacity with people who appeared eager to spend as much money as they possibly could, the sole object being to swell the Relief Funds, which benefited to the extent of £310 18s. 6d. The keenest business men in the market made the bidding, and ran up prices to many times the actual value of the lots, and frequently, when lots were knocked down, the purchaser would call out to the auctioneer to "sell them again." The crowning lot of all was one large Peasgood's Nonsuch Apple, which weighed 30oz. The first bid was £5, but the grand figure of £55 was reached in a few minutes, the purchasers being Messrs. Adam and Co., Bond Street. Fifty-five shillings for a dozen Peaches, £3 15s. for three Pumpkins, £4 5s. for eighteen Apples, and 6 guineas for a basket of mixed fruit were among the average prices realised, and, when everything else was sold, the auctioneer offered his hammer, which brought in another 5 guineas.

Apples in America.—The Apple crop in the Montana, Idaho, Washington, Oregon and California districts, according to the United States Department of Agriculture, is estimated at 18,600,000 bushels, but the Fruit Exchange and papers claim that the production will not exceed 10,700,000 bushels. The prices are very low compared with last year, Jonathan Apples being bought from the grower at 3s. 1d. per bushel, while last year the same two first grades were worth 5s. 2d. per bushel.

Royal Horticultural Society's Exhibitions.—The Rev. W. Wilks informs us that unless some exceptional crisis occurs, the exhibitions of the society will be continued in the Royal Horticultural Society's Hall at Vincent Square, and the year's programme, as it appears in the Book of Arrangements for 1914, be completed.

A Good Single Dahlia.—One of the best single Dahlias for bedding is named Little Othello. This has a fine, branching habit, and flowers very freely over a long period.

A BOWL OF HYACINTHS GROWING IN FIBRE.

The blooms are not over-large and bright scarlet in colour, the dark, bronze green foliage making an excellent foil for the flowers. It is worth making a note of for planting next spring.

Rose Mrs. A. R. Waddell in Autumn.

Although the flowers of this charming Rose come nearly white during the hot days of summer, they are particularly charming in the autumn, when they are freely produced by established plants. At this season they come a beautiful

shade of rich apricot yellow, and are worth growing for their colour alone. The bushes are moderately vigorous and not over-addicted to mildew. This Rose was raised by M. Pernet-Ducher and sent out in 1908.

Flower-Beds for the Spring.—Now that the time for planting beds for spring effects is with us, we would draw the attention of our readers to the article on this subject which appears on page 503. This is written by Mr. J. B. Stevenson, the head-gardener to the Bournemouth Corporation. Visitors to that Southern resort will remember the beautiful effects obtained by Mr. Stevenson in the Chine Gardens and many other open spaces, where the flower-beds, both in the spring and summer, are generally admitted to be among the finest in the country. In our next issue we hope to publish details of the arrangement of the plants by Mr. Stevenson.

Belladonna Lilies and Zephyranthes candida.—One of the most charming features at Kew just now is a long, narrow border, under the south wall of House No. 1, that is filled with the Belladonna Lily, Amaryllis Belladonna, and edged with a double row of Zephyranthes candida. The pink flowers of the Belladonna Lilies are particularly good, and harmonise well with the white blooms of the Zephyranthes. The green, Rush-like foliage of the latter makes an excellent foil for both, and does away to some extent with the bareness that would otherwise prevail on account of the natural absence of the Amaryllis foliage at this season.

Hyacinths in Glazed Bowls.—The illustration on this page serves to remind us that it is quite time that all bulbs to be grown in glazed bowls filled with fibre should be put in without further delay. The process, which is really very simple, has been so often dealt with in detail in our pages that it is not necessary now to say much about

it. The fibre should be nicely wet, not sodden, and the bulbs placed so that they nearly, but not quite, touch each other. When completed, the "nose" of each ought to be showing just above the surface of the fibre. Although large bedding Hyacinths are so often used, we prefer the more graceful miniature set, bulbs of which can be purchased from any of our advertisers. Daffodils, Tulips, Snowdrops, Crocuses, Fritillaries and, indeed, almost any kind of bulb can also be grown in bowls of fibre.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Recipe for Green Tomato Pickle.—Place two and a-half pounds of sliced green Tomatoes in a jar, and sprinkle salt over each layer of slices; let them remain twelve hours, drain off the salt water, and pour over them as much vinegar as will cover them. Add a quarter of a pound of brown sugar, one-eighth of bruised ginger, one-eighth of cloves, one-eighth of mustard seed and a quarter of a teaspoonful of dried chillies. Simmer all together till the Tomatoes are quite soft, then bottle and cork well, and keep in a cool place. **Recipe for ripe Tomato chutney:** One pound of moist sugar, one ounce of ground ginger, half an ounce of salt, half a pound of raisins, two cloves, two large Onions, two pounds of Apples, one pound of Tomatoes, one-eighth of cayenne pepper and one and a-half pints of vinegar. Peel and chop Onions and Apples, stone raisins and chop

mostly planted as reserves in order to obtain, if possible, healthy cuttings. To my surprise these, in the varieties George Home, Crimson Gem and Mrs. F. Fulford, have flowered profusely; the spikes are most handsome and no disease is apparent. I obtained a good stock of cuttings, too, and I have recently lifted all the best plants—there was not space available for all—which had previously been topped. Nice balls of soil were secured to the plants, and they were closely arranged in cutting-boxes. In the meantime, and until severe weather indicates the wisdom of housing them, they are standing in a sheltered position out of doors. They are wintered in a slightly warm structure. The cuttings root with the greatest facility in a propagating-pit.—R. P. BROTHERSTON.

Kniphofia caulescens.—There are one or two species of Kniphofias that differ from the majority by their caulescent habit. One of the most distinct of these is *Kniphofia caulescens*, with its large rosettes of glaucous foliage, which are borne on stems often 3 feet from the ground, until their weight pulls them over, when they

juice is gone again, but not dried up. Then pour on enough vinegar to cover them, with a little mace, peppercorns and a little cayenne pepper if preferred; make them boil about three minutes; then turn out and cover.—ANNE AMATEUR.

A Heavy Crop of Melons.—The following may interest your readers: Sixty-one Melons, weighing altogether 105lb., were grown in a cold frame (four-light). The plants were raised from seed of Sutton's Ar and Emerald Gem, and were grown by Mr. Watkins, gardener to Dr. and Mrs. Armstrong-Jones, Plas Dinas, Carnarvon, North Wales.—C. W.

Royal Horticultural Society's Fruit Show.—It was with very great regret that the Council were compelled to abandon the British-grown Fruit Show fixed for September 29, but the military were then in occupation of the hall, and no other suitable hall could be discovered which was not similarly occupied. The Council have now received an assurance that their hall will not be further taken over except under pressure of some altogether unexpected and grave crisis in affairs, so that we may now with a fair amount of confidence resume our regular meetings and shows. It is now too late to attempt to reorganise the whole of the fruit show according to the published schedule, but under the peculiar circumstances the Council think it a good opportunity to draw attention to the more definitely late-keeping varieties of British hardy fruit. They therefore specially invite exhibits of such, both as collections and as single dishes, on Tuesday, December 1. No schedule will be issued, but the Council will make such awards as they think fit. They are anxious to utilise this opportunity of laying stress on the really and naturally late-keeping varieties, and, consequently, will not look with favour on earlier varieties, either artificially or with great and exceptional care, kept back out of season.—W. WILKS, Secretary.

Belladonna Lilies in Ireland.—We have grown these for many years, but I think this has been a record season for flowering. On a patch of ground in a very dry border, and less than two yards square, a group of plants has produced eighty flower-spikes, carrying from six to seven blooms on each, almost all of which are now fully expanded and a sight not easily forgotten. The flowers vary from almost pure white to a reddish hue. They flourish in a rich, deep, sandy soil, and the best time to plant a stock is June. They should not be again disturbed for years, and will ultimately establish themselves and produce masses of blossom. All that is necessary in the growing season is to give them a few good waterings of clear water and an occasional watering with liquid manure. The leaves and flowers do not come together; the former are produced in the early spring, and should be in some way protected from frost, as they are not quite hardy. We had a fresh supply of bulbs of this Lily given us by the late Lord Wolseley, who brought them from South Africa. They differ slightly from those we have previously grown, and have bloomed equally as well, the colour of the flowers being of a deeper shade of pink and somewhat smaller. All the leading botanists agree that *Amaryllis Belladonna* was introduced into the British Isles from the West Indies in 1712, and it is very probable that it was brought from England to the Cape of Good Hope, but we have no authentic information as to its being ever found growing naturally there.—SAMUEL BRYAN, *The Gardens, Fortfield House, Terenure, County Dublin.*

KNIPHOFIA CAULESCENS IN THE CAMBRIDGE BOTANIC GARDEN.

fine, skin Tomatoes; mix all ingredients together and boil until tender; time, about two and a-half hours; quantity, six pounds.—R. A. CARTER.

The Rock Garden in Late Autumn.—I saw in your issue of THE GARDEN for October 3 a paragraph on flowering plants in the rock garden at Kew, and I think you may be interested in the following list of plants now flowering in my rock garden here, which is situated 900 feet above sea-level, in peat soil, and made in October, 1913: *Violas* (mauve and white), *Aubrietias* (purple, mauve and Fire King), *Phlox amoena*, *Saxifraga aizoides rubens*, *Helianthemums* (rose, scarlet and white), *Veronica rupestris*, *Verbena*, *Sedum pulchellum*, *Achillea Kellereri*, *Primula cashmeriana*, *Sempervivum Fauconettii*, *Thymus alpinus*, *Calamintha* and *Crocus speciosus Aitchisonii*.—(Mrs.) LORNA WILSON, *Huccaby House, Princetown, South Devon.*

A Note on Pentstemons.—During a very long period I have had great difficulty in keeping named Pentstemons, the plants becoming diseased throughout the flowering stage, and shoots for cuttings failing to be produced. In spring I rooted a large number of shoots provided by old plants preserved over the winter, and these were

root along the stem, the crowns again commence to grow up, and in this way they soon form a large mass. Though less brilliant than most of the other Flame Flowers, it is quite an attractive plant with its glaucous, blue-grey foliage, which is ornamental the whole year through, while in June it produces on scapes, from 4 feet to 5 feet high, dense heads of flowers 12 inches to 18 inches in length, which are reddish salmon in their early stage, the flowers when fully expanded gradually becoming white, tinged with greenish yellow, and producing an effective contrast. It is a native of South Africa, whence it is said to have been introduced in 1862 from the Stormbergen Mountains. Seeds are produced quite freely, but, like those of many other liliaceous plants, should be sown as soon as ripe, while suckers or offsets root freely if taken off and put in sand in a cool frame early in the autumn or in the spring.—F. G. PRESTON, *Cambridge Botanic Garden.*

Pickled Mushrooms.—Mrs. Hobden's recipe: With a piece of coarse flannel and salt rub each Mushroom well (which must be buttons); then thoroughly dry them, put them in a saucepan (with a sprinkling of salt to make the juice run) over a slow fire. Let them simmer until the

SOME HINTS ON SPRING BEDDING.

THE planting of spring-flowering plants in beds and borders is becoming more fashionable each year. From the numerous enquiries I receive respecting the various plants used in the public gardens here, and how they are prepared and planted, I think a short article on the subject in your valuable paper would be acceptable. The variety of plants and bulbs used here is not very large. The aim has been to use only such plants as are easily produced in quantity and the cheaper varieties of Tulips, Hyacinths and Narcissi. The following are the principal plants I use, viz., Wallflowers, Polyanthuses, Daisies, Myosotis and Violas, Alyssum, Aubrietias and double Arabis.

Wallflowers are grown from seed sown in drills 1 foot apart at the end of April or the first week in May. I may state that the soil is light, and, previous to sowing the seed, the ground is trod firmly and raked with a wooden rake. The young seedlings are above the ground in a few days, and the Dutch hoe is freely used until they are ready for transplanting. During June the ground is dug in readiness for their reception, only a small quantity of manure being used. Lime and wood ashes are added when necessary. When the plants are 4 inches to 6 inches high, the prepared ground is harrowed with a small harrow, rolled with a light roller, and again harrowed. Firm ground, with the use of soot and lime, is the best antidote for the prevention of club-root. The plants are put in rows 1 foot apart and 6 inches from plant to plant. If the weather is dry, they are given a good watering (there is no waiting for rain). The Dutch hoe is freely used; and they make large bushy plants by the middle of October.

Polyanthuses are raised from seed sown in boxes in February and placed in a cold frame. As soon as the seedlings are large enough, they are pricked out in other boxes and stood outside, and afterwards planted in rows similarly to Wallflowers. As Polyanthuses are gross feeders, a heavier dressing of manure is given where they are planted.

Daisies.—These are sown in June in boxes, placed in a cold frame, pricked off in other boxes, and afterwards planted in beds 4 feet wide and 6 inches from plant to plant.

Myosotis is sown in July on a shady border, and afterwards planted out in rows 9 inches wide and 6 inches apart in the row. In sowing the seed of Myosotis, care should be taken not to cover it too deeply. Scatter the seed thinly, beat the bed with the back of a shovel or spade, and give a very slight sprinkling of fine sifted soil.

Pansies and Violas are grown from seed sown early in June. Treated in the same way as Daisies, they are in flower when planted out in their permanent quarters in October.

Alyssum is also grown from seed sown in boxes in March. When large enough the seedlings are pricked off in other boxes and afterwards planted in rows the same as Polyanthuses. These make fine plants by October.

Aubrietias are grown from division in March and August. In March store plants are lifted, their long roots shortened and divided into pieces of several shoots each, and planted in rows 1 foot apart and 6 inches from plant to plant. A few

weeks later the rows of plants are well trodden with the foot on each side. The plants soon grow away and are usually in fine flower in June. In July the tops are cut off with sheep shears, leaving them 2 inches to 3 inches high. These soon break out and make fine bushy plants, 6 inches to 8 inches through, by October. Those divided in August are the plants taken from the flower-beds in June. Before lifting, the tops are cut off, as above. After lifting, the roots are well cut back and the plants laid thickly in rows in a shady place. By the end of July these have broken out nicely, and are then divided and planted out in nursery beds in a similar way to Daisies. These also make fine plants, but not so large as those divided in March. Aubrietias can also be grown from seed, but they seldom come true; nevertheless, they make a nice bed, if not so uniform. Sow the seed in boxes in April and treat in a similar way to Pansies and Violas, and the result will be good plants at the same time as those from division.

Double Arabis is grown from cuttings put in boxes in July and placed in a frame, kept moist and shaded, and afterwards planted out in rows like Myosotis. The cuttings are taken from reserve plants that have been cut down close to the ground after flowering. The young growths, about three inches long, are used as cuttings. Good plants can also be grown from pieces of the old plants dibbled in in rows on a shady border in July.

Chine Gardens, Bournemouth.

(To be continued.)

SWEET PEA GROWING CONSIDERED.

"The best laid schemes o' mice and men
Gang aft agley."

TO-DAY should have been spent at a Dahlia show, but the war has caused it to be cancelled, therefore I have seized the opportunity for a day's recuperation and enjoyment in the glories of a garden. And what a perfect day it is! An azure sky dotted with fleecy clouds, a softly sighing south wind and a brilliant sky belie the calendar; while the lawn, transformed by the recent showers, and the Rose-beds still rich in abundance of beautiful flowers, combine to delude one that it is a June day. Close by one hears the hum of bees working among the Honeysuckle and Jasmine on the archways; and why does a fully painted Admiral butterfly need to settle beside one and turn one's mind to other scenes where war and not peace reigns? Yet as one's gaze wanders to a few clumps of Sweet Peas still carrying a few blossoms, one turns from dreams to realities. Will all be well with our favourite? Will people become too economical and neglect their gardens and forget that business must be carried on as usual? With such thoughts breaking in upon my musings I cannot resist taking my pen, and I hope these few words will exhort those Sweet Pea lovers who know the worth of their favourite to send immediately to the seedsman an order, and, as far as possible, to accompany that order with a settlement of all former accounts, for it is only by these means that business can be carried on through the troublesome days that lie before us. The war will affect everyone, but each can do his

share to co-operate with his brother that we suffer together, and later on we shall also reap the harvest of Peace together. Before, however, I introduce you to my best friends, I would tell you especially that if you do not appreciate Sweet Peas as you should, you are missing so very much that helps to make the joys of life richer and more abundant.

It may be that the war will continue for many months, and the toll of brave fellows it will take will undoubtedly be heavy. Consider, then, the amount of pleasure you will be able to give those sufferers if you can supply them with abundance of flowers. The study and contemplation of the beautiful in any of its manifold forms is always an absorbing interest, but when beauty is materialised in a bunch of Sweet Peas, then it becomes, beyond measure, more fascinating. We also know that every beautiful thing transmits, by a marvellously subtle power, its influence all around; so to those who are seeking some small way of helping their country I suggest that they maintain their gardens as before, and, if possible, grow more Sweet Peas, for no flower has a greater charm nor a more benign influence.

Of course, to attain personally this admiration for and love of Sweet Peas, it goes without saying that one must be thoroughly acquainted with the different varieties individually, and this is impossible until you have grown them more or less indifferently, have experienced the shocks of keen disappointment, and likewise have tasted the ecstatic thrills of success. And it is this which makes Sweet Pea growing so wholesome and energising, physically and morally. You cannot grow Sweet Peas without trouble, and the fascinating expectancy which compels one to get up "with the lark" to see whether one's efforts have been crowned with success ever urges one onwards to greater heights. There is, therefore, no finality in Sweet Pea growing. Having succeeded with one variety we select another, and each year brings a new friend to be cherished and firmly established in our affections. Thus grows the boundaries of the heart, until the whole world of flowers is enthroned and beauty envelops us on every side.

Yet there is a risk in Sweet Pea growing, and the risk is that it may so enthrall us that we chafe at the winter frosts which destroy our favourites out of doors. But this is a risk to be approved and fostered, as the Sweet Pea is so amenable to all kind culture that it will flourish under glass at Christmas and onwards, and, combined with the winter-flowering varieties that are now being put upon the market, a perpetual supply of flowers all the year can be maintained.

I hope I have said enough to convince all readers of the intrinsic value of the Sweet Pea, and for those who have not yet fallen under the yoke and thralldom of the Queen of Annuals I add a few words of cultural guidance.

Seed.—It is essential that seed be procured from a firm of established repute. Unfortunately, the "boom" in Sweet Peas created many "jerry growers," whose one aim was to get rich quickly, and they foisted on the market such "mixtures" which well-nigh destroyed the faith of many. Firms whose advertisements appear in *THE GARDEN* can be relied upon, and an order, with remittance, should be posted without delay to the one selected. In choosing varieties, whose name is legion, the beginner should be guided either by the seedsman or some Sweet Pea lover

who knows what is best. I suggest the following to one who intends growing for a plentiful supply of decorative blossoms: Etta Dyke or King White, Maud Holmes, R. F. Felton, Rosabelle, Lavender George Herbert, Elsie Herbert, Lord Nelson Spencer, King Manoel, Hercules, Elfrida Pearson, Mrs. Cuthbertson and Margaret Atlee. Undoubtedly the pinks are the most popular, and I have excluded all salmon and fancy varieties, as I do not consider them (beautiful as they are) suitable for garden decorative display.

WISTARIA CHINENSIS GROWING OVER A GRANARY.

In former notes I have dealt fully with the advantages of autumn sowing and the need for deep cultivation of the soil, but I would add that, for ordinary purposes, Sweet Peas will thrive well if given fair conditions and ordinary culture. For exhibition flowers rich soil is necessary, but everyone can grow good Sweet Peas if he learns to love them and give them ordinary care. A little too much attention has been given to the Sweet Pea from the exhibition standpoint, and while not lessening in a single degree the value of the Sweet Pea as an exhibition flower, yet one would like to emphasise the fact that the Sweet Pea is essentially a garden decorative flower, and as such cannot be excelled by any other. In the future, when so much joy may possibly be the outcome of a bunch of Sweet Peas, this will be lacking if the ordering and planting of seeds is not done as usual. The war necessitates the curtailing of luxuries, but the supply of the garden is no luxury, rather a necessity. Let us each look ahead and see the ultimate issue of Right over Might, and contribute our share by maintaining a full and plenteous garden. S. M. CROW.

SOME RECENTLY INTRODUCED SWEET-SCENTED ROSES.

(Continued from page 492.)

Alice de Rothschild (1910) is a good yellow Tea Rose with something of the Maréchal Niel colour and scent.

Claudius (1910), a gold medal Rose, is of moderate, rather stumpy growth, with large flowers of bright rose colour and of true Rose scent.

Mrs. H. E. Coxhead (1910), a gold medal Rose, though of fine form and delicious fragrance, is of such a dull magenta red shade that a standard or two is as much as one cares to have of it in the garden. Sometimes in October or November the buds come a brighter colour.

Lady Hillingdon and **Mrs. Foley Hobbs** (both introduced in 1910) have quickly made their way into our gardens, the one for the sake of its deep orange flowers and ruddy foliage, the other for its occasionally perfectly shaped ivory white blooms so useful to the exhibitor. Both have a very delicate and pleasant Tea scent.

Rayon d'Or (1910), the wonderful yellow Rose of M. Pernet-Ducher's, has a very pleasing fragrance, reminiscent of ripe Apricots.

The year 1911 produced several fragrant Roses.

Desdemona. — Deep pink. A strong grower.

Edward Mawley. — A gold medal Rose. Rich crimson, shaded blackish scarlet. Might be a good doer where it can be kept free of black spot, to which it seems specially prone.

Elizabeth. — Another pink Rose of more refined shape than Desdemona.

Florence Haswell Veitch. — A vigorous grower, doing well as a dwarf pillar. It has good dark green foliage and well-shaped scarlet-crimson flowers.

Mrs. Edward Powell. — A delightful bedding Rose of vigorous, upright habit, splendid metallic-hued foliage, and very bright red, sweet-scented blooms. The fragrance of Mrs. E. Paull is quite distinct, very decided, and though not so sweet as that of Richmond, is most refreshing.

The year 1912 appears to have added only one Rose to my list, and that is

George Dickson, a very strong-growing Hybrid Tea. In many respects it is more like a Hybrid Perpetual. It has massive, fragrant blooms of velvety crimson, often marked with a splash of white. Unfortunately, it is rather apt to hang its head, very apt to be attacked by mildew, and is not free in the autumn.

The last two varieties I have noticed as being specially fragrant are Mrs. Andrew Carnegie and H. E. Richardson. They are 1913 Roses, and so, unlike the others I have mentioned, have not been grown in my own garden, but I have seen and smelt them at a good many shows.

Mrs. Andrew Carnegie, a gold medal Rose, is an exhibition Rose only, I fear. Its huge lemon yellow blooms are made up of masses of thin petals, which I feel sure would not stand much "weather." It was called, when first shown, the sweet-scented Frau Karl Druschki, and it will probably be disappointing to many to find that it has not Frau Karl Druschki's vigour and rain-resisting qualities.

H. E. Richardson, a deep crimson Rose, was well shown at the National Rose Society's autumn show last September. If I remember rightly, a market basket was filled with its deliciously fragrant blooms. I was told that it is disappointing in the garden, but the colour was so good and the scent so surpassingly sweet that when it can be bought for a couple of shillings it will be well worth trying by those who, like myself, look upon fragrance as one of the most endearing qualities of the Rose.

WHITE LADY.

SOME GOOD ROSES FOR HEDGES.

IN recent years there has been an increasing demand for Roses of vigorous habit suitable for growing as low, informal hedges. In many good gardens now it is usual to find a hedge of this kind forming a boundary to the Rose garden or a dividing line between kitchen and flower gardens, and when suitably placed and the right varieties selected, few features are capable of providing such pleasing and harmonious results. The Sweet Briars and the Hybrid Penzance Briars have for a long time been used for this purpose, almost to the exclusion of other varieties, and, beautiful and suitable as they are, these single-flowered fugacious kinds do not meet everyone's requirements. There are a good many large-flowered Roses well adapted for planting as informal hedges. One of the best, and one that is not grown half so much as it ought to be, is the Thornless Rose, Zephyrine Drouhin. It quickly forms a tall bush or small pillar, and flowers freely, both in summer and autumn, its deliciously fragrant blossoms possessing a charming shade of bright rose pink such as we get in no other variety.

A small hedge that I planted three years ago is composed of Grüss an Teplitz and Gloire de Dijon. The bushes are now over 6 feet high, although when planted they were pruned within a few inches of the soil. The varieties were planted alternately, about fifteen inches apart, and from the end of May until well into November are never without flowers. Apart from the beautiful effect in the garden, this hedge yielded an abundance of good blooms for cutting. Although Gloire de Dijon is a Tea Rose, it is quite hardy, is one of the earliest to start flowering and almost the last to finish. These attributes and its delicious Tea scent more than outweigh the faulty shape of many of the blossoms, a drawback that condemns it in the eyes of many ardent rosarians. Grüss an Teplitz, with its large bunches of scarlet, fragrant flowers, is too well known and appreciated to need further comment. J. B. Clark, with large crimson

flowers; Longworth Rambler, bright cerise; Warrior, crimson scarlet; W. A. Richardson, apricot yellow; Gustave Regis, nankeen; Mme. Isaac Pereire, a fine old, sweetly scented Bourbon Rose of pink shade; Conrad F. Meyer, soft pink, very large flowers; and Blanc Double de Coubert, white, are a few other more or less large-flowered Roses that might with advantage be used for hedges such as we now have under notice.

These hedges are by no means difficult to manage, but it certainly pays to thoroughly prepare the soil before planting. Deep cultivation, thorough manuring with good farmyard manure, and a handful of bone-meal mixed in the top 6 inches for every bush, will result in rapid yet sturdy growth that will form a perfect screen in two years. With some of the very strong-growing varieties, such as Gloire de Dijon and Conrad F. Meyer, it is often necessary to put in a few short, stout stakes, and then bend over the longest rods and tie the ends to the stakes. This induces the side buds to burst freely, and a bountiful supply of flowers is ensured. So far as pruning is concerned, the less done in reason the better, except when the bushes are newly planted, when they should be cut almost to the ground level. When established, the cutting away, close to the soil, of some of the oldest wood each year induces the formation of sturdy new rods that keep the bushes in good condition.

H.

FLOWERING CLIMBERS OVER FARM BUILDINGS.

(WISTARIA CHINENSIS AND CLEMATIS MONTANA.)

IT is not until *Wistaria chinensis* attains a good age that it flowers in the greatest profusion, and it is when growing over old buildings that it is seen to advantage, for the atmosphere of age enhances its beauty in no small degree. Happily, the *Wistaria* presents no great difficulties in cultivation. It shows a preference for a deep, loamy soil and a sunny wall, and when once established it grows freely and flowers abundantly. Occasionally in this country it produces seeds, and these are borne in pods resembling Kidney Beans. Sowing seeds is a slow and uncertain method of raising plants, and the mode of propagation usually adopted is to layer the growths produced near to the base of the plants. Layering is best done in the summer, after the flowers are over.

Clematis montana is another beautiful climber, equally at home on the roof of an old building. Both climbers flower at the same time, and they are unsurpassed for beauty and effect. The two accompanying pictures were taken at Summer Farm, West Clandon, early in June. The *Wistaria* is seen growing over a disused granary, while the Mountain Clematis looks very picturesque flowering in almost wild profusion on the roof of an old barn against the dense background of fine old Elm trees. Considering the ease with which *Clematis montana* may be grown in this country, it might almost be imagined to be a native of Britain, instead of which it was introduced from Nepaul in 1831. It is a capital subject for growing over balconies and porches, and it looks very effective if allowed to ramble at will over Pine trees, when the light star-like flowers are shown up in marked contrast to the dark foliage of the conifers. This *Clematis* does well in almost any position, and is not in the least fastidious about soil.

C. Q.

BULBS FOR THE ROCK GARDEN.

DURING the early spring months, and even well into the summer, our rock gardens owe not a little of their charm and interest to the many dwarf kinds of bulbous plants that find a congenial home in the pockets or bays where a goodly depth of loam or peat and loam can be provided for their roots to wander in. Nearly every post now brings catalogues of bulbs, a sure sign that the planting season is at hand; and as a great deal depends upon early planting, it is proposed to enumerate some at least of the many kinds suitable for the alpine garden.

The *Scilla* family alone provides us with several gems that cannot be omitted. The Siberian Squill, *Scilla sibirica*, with rich blue flowers, and its white variety are two plants that will thrive in almost any position where a few inches of good soil can be lodged. *Puschkinia libanotica* is a near relative of these; it grows taller and flowers later, but must be included on account of the quaint china blue markings on its white petals. Then we must not forget the Glory of the Snow, *Chionodoxa Luciliae*, with pale blue flowers, and the rich dark blue variety named *sardensis*. They are both easily cultivated, and seed freely when once established. Of *Anemones* there are a number to select from. The Wood Windflower, *A. nemerosa*, with its lavender-flowered variety *robinsoniana* and the large-flowered Blue Bonnet, should have a partly shaded position and some decayed leaves in the soil. Then there is the Apennine Windflower, *A. apennina*, and the Grecian Windflower, *A. blanda*, both with blue flowers and both admirably adapted for the rock garden. The well-drained places in the rock garden that can easily be filled with good soil make a suitable home for that most gorgeous of Windflowers, *A. fulgens*, which, if protected from north

and east winds, may often be had in flower at Christmas. It is not a kind plant, however, and cannot be relied upon to do well, even under the most favourable conditions. Where it does grow, however, it usually grows well, and is worthy of a trial for the sake of its scarlet blossoms.

Of *Crocuses* there are a number of species admirably adapted for the rock garden. To my mind, the gem of all is *Sieberi*, with soft lavender flowers and bright orange stigmata. In a sheltered corner it begins to flower in January, and continues

for at least a month. Then there is the charming little *C. susiana*, with golden yellow flowers quaintly striped on the outside with maroon. It increases freely when established if left undisturbed. *C. biflorus*, white, with violet markings, and *C. tommasinianus*, with soft silvery lavender grey flowers, are others that certainly ought to be included. Of hardy *Cyclamen* suitable for autumn planting, there are three, viz., *C. cilicicum*, with white flowers; *C. Coum*, rose-coloured blossoms; and *C. ibericum*, which is similar to *C. Coum*, except that the foliage is veined with silver. These ought to be planted at once, and it is well to bear in mind that they appreciate decayed leaves and old mortar in the soil. The Winter Aconite, *Eranthis hyemalis*, ought also to have a corner. It is usually regarded as a common plant, but if the curious little roots are put in now, we shall be rewarded in midwinter with flowers of rich buttercup yellow, each surrounded by a quaint ruff of green foliage. Snowdrops of several kinds are available, though, to my mind, none is more suitable than the common one, *Galanthus nivalis*. Of the wild Tulips of other countries, there are

THE MOUNTAIN CLEMATIS (*C. MONTANA*) VEILING AN OLD BARN

several beautiful and interesting kinds suitable for our purpose, the most charming of all being the Water Lily Tulip, *Tulipa kaufmanniana*. It has creamy white flowers with rich yellow centres, and when fully expanded these resemble miniature Water Lilies. It needs good soil and a sunny position. The Persian Tulip, *T. persica*, which rarely grows more than 3 inches high, is a gem for the rock garden; it has yellow flowers with golden bronze exteriors. Dog's-tooth Violets are a fairly large family, and of the common one, *Erythronium Dens-canis*, which has purple flowers,

there are a number of varieties, Frans Hals, with large purple blossoms, and La Neige, white, being two of the best. They appreciate a partially shaded position and rather deep planting. *E. californicum*, pale yellow; *E. Hendersonii*, pale lilac, with purple centre; *E. Hartwegii*, pale yellow; and *E. revolutum Johnsonii*, rose with yellow centre, are all beautiful kinds from America. Dwarf Irises, such as *I. Heldreichii*, with lavender and violet flowers; and *I. reticulata*, with deep violet-coloured blossoms that emit a delightful fragrance, must find a home in the rock garden.

The Grape Hyacinths, or *Muscari*, are most useful for creating bold masses of colour, particularly the one known as Heavenly Blue. If planted freely in good-sized drifts it will make a picture of gentian blue in spring that will more than repay us for the slight trouble that planting entails.

Of dwarf *Narcissi* there are many kinds, though none is quite so charming as the dainty little *minimus*, a perfect Daffodil of pygmy size and golden yellow colour. *Cyclamineus*, minor, *juncifolius*, *moschatus*, *triandrus calathinus* and *Queen of Spain* are others that ought to be included. S. X.

THE SNOWDROP.

OF all the flowers that come to us in the early days of the year, none is more highly appreciated than the Snowdrop.

The simplicity of its pure, glistening white blossoms, swaying, sometimes none too gently, in the cutting winds of winter, appeals to young and old alike, and it is a flower that has not, so far as I know, a single human enemy. Nor is it one that has any bad traits, unless the tendency of the bulbs of such species as *Elwesii* to die out under any except the most favourable conditions can be regarded as one. Indeed, the Snowdrop is one of the easiest of our hardy plants to cultivate, and will thrive for several years at least under the most adverse conditions.

Undoubtedly the most effective place for this dainty little flower is the shrubbery, woodland or grassland, situations where the bulbs can be allowed to remain undisturbed and to multiply and increase in vigour year after year. There is a great charm in the contrast between the massive trunks of Elms and other trees of the woodland and this delicate-looking, though in reality hardy, flower that no other grouping, even that of the shrubbery and grassland, can give us. In the woodland, too, the dead leaves are usually allowed to remain on the ground, there to form miniature drifts that emphasise, as it were, the purity of the whiteness of the Snowdrop blooms.

To the uninitiated all Snowdrops appear much the same, yet there is, on closer investigation, a good deal of difference between the various species, many of which are by no means well known. Our native Snowdrop, *Galanthus nivalis*,

is, naturally, the most common of all, and the best for naturalising in the woodland or grass. It is a variable species, the best-known variety being that with double flowers. There is also an extra large-flowered and strong-growing variety of it known as *G. n. Imperati*, which is worthy of inclusion in every garden, though as yet too choice for naturalising. Another variety of the common Snowdrop, named *G. n. octobrensis*, usually flowers in November, but has a tendency to die out rather quickly in most soils.

Next in popularity to our common Snowdrop is the large and beautiful *G. Elwesii*, a native of Asia Minor. This, like the common Snowdrop, is very variable. It differs from the common

rendering it quite distinct. It does not, however, flower so freely in many places as *G. nivalis* and *G. Elwesii*. There are several other lesser-known species and a great number of varieties, most of which are too rare and expensive to allow of them being generally grown. One of the most beautiful of these is *G. Allenii*, which has very broad, arching leaves and large blossoms. It needs a warmer position than most other Snowdrops. For some years past a few enthusiastic cultivators of these flowers have raised hybrids by crossing several of the species before named, but none of these that I have seen surpass for general utility and beauty the two species *nivalis* and *Elwesii*.

To ensure the bulbs flowering well another year, it is essential that they be well and gradually ripened after their flowering period is over. The earlier they are planted now the better, because the bulbs, being small, suffer considerably if kept out of the soil for any considerable time. Most, or all, of those named can be purchased from any of the dealers who advertise bulbs in THE GARDEN. G. S.

THE WATER LILY TULIP (*TULIPA KAUFMANNIANA*). NOW IS THE TIME TO PLANT.

THE WATER LILY TULIP.

THIS beautiful Tulip is almost, if not quite, the first of its race to open in spring, the blossoms in a normal season being fully developed before

March has departed. It is a delightful Tulip in every respect, and one can only assume that it is because it is not well known that it is so seldom grown. Its botanical name, under which it is usually listed in bulb catalogues, is *Tulipa kaufmanniana*, but owing to the half-opened flowers closely resembling those of a miniature Water Lily, it is often referred to in gardens as the Water Lily Tulip. The petals are deep cream at the uppermost parts, the centre of the flower being rich golden yellow. Frequently the exterior is striped rich carmine, and the blossoms are slightly fragrant. It is not a difficult Tulip to grow, but the bulbs ought to be planted comparatively early, *i.e.*, during September or October, at a depth of about four inches. As its full beauty is

only revealed when the flowers are partly open, it should be planted in a position where the sun can reach it for the greater part of the day. Almost any good garden soil suits it, except that which is waterlogged. In addition to the type plant there is a very beautiful variety named *T. kaufmanniana aurea*. As its varietal name indicates, this has blossoms of rich golden yellow, handsomely feathered on the exterior with scarlet. At present it is too rare for general cultivation outdoors, but it is a charming plant for growing in pots for the conservatory, the bulbs being potted up in ordinary potting soil in September or October and treated in the usual way adopted with other Tulips and Daffodils grown in pots.

The Crimean Snowdrop, *G. plicatus*, is known in many gardens in this country, its rather broad leaves with their plicate or folded back edges

one in having green inner segments and bolder stature, and owing to the latter feature it is, in many gardens, taking the place of *G. nivalis*. It, however, requires lighter soil and is not so useful for planting in grass, the bulbs having a tendency to become blind after they have been planted a few years. The variety known as *G. E. Cassaba* is even more vigorous than the type, the leaves and flower-stems, when grown in the rather heavier soil that it seems to require, frequently attaining a height of 1 foot.

THE LITTLE GARDEN.

RESULTS OF OUR COMPETITION.

AS was no doubt inevitable, the National Crisis, which was at its height during August, prevented some of our readers who had notified their intention of sending in designs from doing so before September 1, the last day of entry. The labours of the Judges in examining the designs received (to the number of about four hundred) were, however, by no means light, and we now have pleasure in printing their report and awards.

WE have examined carefully the designs in THE GARDEN Competition for Planning and Planting the Little Garden. Having taken into account the general conditions laid down, we make the following awards:

FOR SITE No. 1.

- First Prize of 5 guineas** to MR. A. TROYTE GRIFFITH, The Priory Gateway, Malvern.
- Second Prize of 2 guineas** to MR. BURNETT N. K. ORPHOOT, 25, Queensferry Street, Edinburgh.
- Third Prize of 1 guinea** to MISS ELIZABETH LEONARD, 46, Abbot Buildings, Cambridge, Mass., U.S.A.

Book prizes, each to the value of half-a-guinea, to Mr. Kenneth Dalgliesh, 165, Fenchurch Street, E.C.; Miss I. Grant Brown, Castle Hill, Lancaster; Miss Isobel R. Harding, Vilmore Cottage, Petersfield, Hants; Mr. Archie G. Paton, 44, Apsley Street, Partick, Glasgow; Miss B. M. Cory, 9, Elm Grove Road, Ealing, W.; and Mr. George L. Morris, 40, Finsbury Square, E.C.

FOR SITE No. 2.

- First Prize of 5 guineas** to MR. GEORGE L. MORRIS, 40, Finsbury Square, E.C.
- Second Prize of 2 guineas** to MISS I. GRANT BROWN, Castle Hill, Lancaster.
- Third Prize of 1 guinea** to MR. HUGH R. DIXON, 73, Corringham Road, Golders Green, N.W.

Book prizes, each to the value of half-a-guinea, to Miss Norah Geddes, Outlook Tower, Edinburgh; Mr. Kenneth Dalgliesh, 165, Fenchurch Street, E.C.; Mr. H. A. Rowbotham, 3, Onslow Road, New Malden, Surrey; Mr. Walter J. Wills, 139, Barry Road, Dulwich, S.E.; and Mr. John A. Weall, Kimberley Road, Borrowash, Derby.

FOR SITE No. 3.

- First Prize of 5 guineas** to MISS I. GRANT BROWN, Castle Hill, Lancaster.
- Second Prize of 2 guineas** to MISS ELIZABETH LEONARD, 46, Abbot Buildings, Cambridge, Mass., U.S.A.
- Third Prize of 1 guinea** to MR. KENNETH DALGLIESH, 165, Fenchurch Street, E.C.

Book prizes, each to the value of half-a-guinea, to Mr. G. L. Thornton Sharp, 626, Pender Street, W., Vancouver, B.C.; Mr. Hugh Dixon, 73, Corringham Road, Golders Green, N.W.; Miss Norah Geddes, Outlook Tower, Edinburgh; and Mr. Ernest J. Biggs, 215, Antrobus Road, Handsworth, Birmingham.

FOR SITE No. 4.

- First Prize of 5 guineas** to MR. JOHN HATTON, Wentworth Road, Four Oaks, Sutton Coldfield.
- Second Prize of 2 guineas** to MISS ISOBEL HARDING, Vilmore Cottage, Petersfield, Hants.
- Third Prize of 1 guinea** to MR. A. TROYTE GRIFFITH, The Priory Gateway, Malvern.
- Book prizes, each to the value of half-a-guinea, to Mr. Burnett N. K. Orphoot, 25, Queensferry

Street, Edinburgh; Mr. Hugh Dixon, 73, Corringham Road, Golders Green, N.W.; Miss I. Grant Brown, Castle Hill, Lancaster; Miss Norah Geddes, Outlook Tower, Edinburgh; and Mr. G. L. Thornton Sharp, 626, Pender Street, W., Vancouver, B.C.

A high level of merit is shown in the designs to which prizes have been awarded, and we have been impressed by the great care and wide knowledge of practical garden problems which have been exhibited by the competitors.

(Signed) GEORGE DILLISTONE.

S. T. WRIGHT."

Cheques for the twelve cash prizes amounting to £33 12s. have been posted to the successful competitors, and the winners of the twenty book prizes have been invited to make their choice from the *Country Life* Library of Gardening.

The especial thanks, not only of the Proprietors of THE GARDEN, but also of the competitors, are due to the Judges for the considerable time and pains which they have devoted to the examination of the plans and to the consideration of the awards.

The following articles on the prize plans are contributed by Mr. Lawrence Weaver, Architectural Editor of *Country Life*; by Mr. George Dillistone; and by Mr. F. W. Harvey, Editor of THE GARDEN, three of the five Judges.

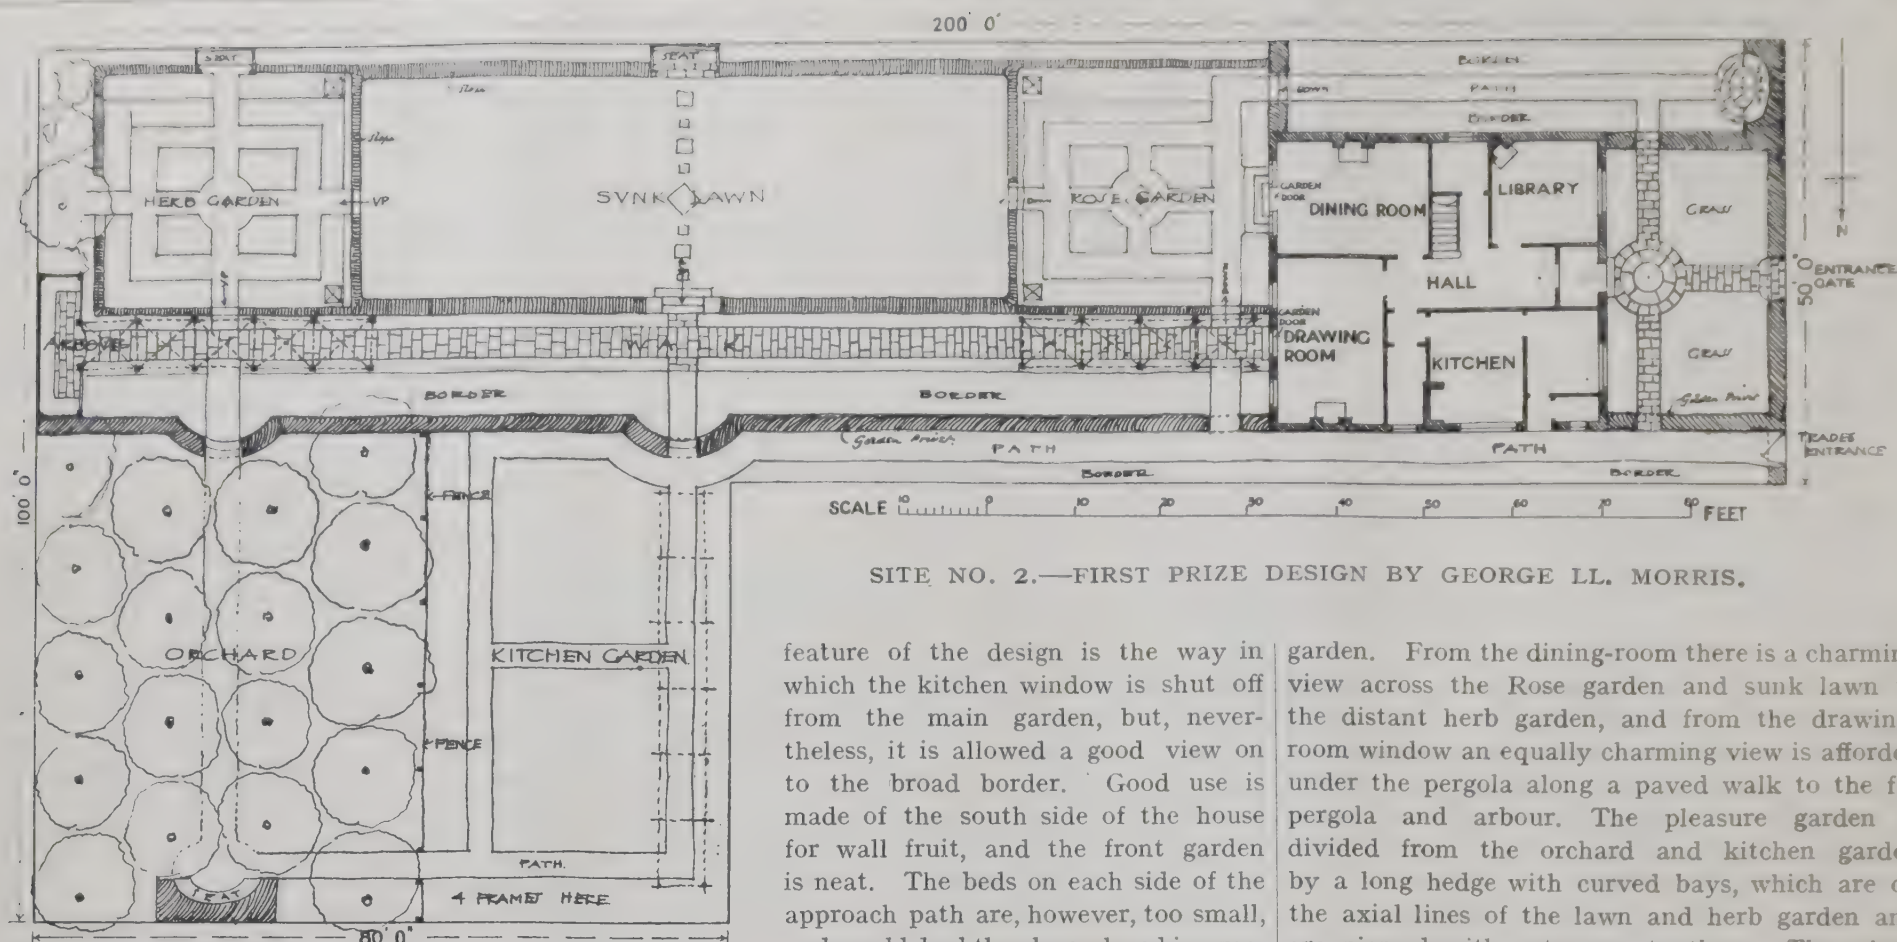

NOTES ON THE WINNING DESIGNS.

Before examining the prize-winning designs in detail, it is worth while drawing attention to some interesting points about the winners. Thirty-two prizes in all were offered, and these have been won by seventeen competitors. The most successful competitor of all is a lady, Miss Grant Brown, who took one first prize, one second prize, and two book prizes. Three competitors—Miss Norah Geddes, Mr. Hugh Dixon and Mr. Kenneth Dalgliesh—each won three prizes. Miss Geddes is the daughter of Professor Patrick Geddes, whose illuminated enthusiasm has done so much for the art of town planning, with which garden design is closely allied in principle. Six competitors took prizes for two sites each, and seven took a single prize. These figures go to show to how great an extent quality in design tells, however much the problem may vary. Twenty-two prizes went to English readers and six to Scottish. Ireland and Wales scored nothing. It is interesting to note that two of the prize-winners hail from the United States and from Canada respectively.

Although the competitors were not asked to give their occupations, there is evidence that several architects entered, and among them Mr. Troyte Griffith succeeded in obtaining the first prize for Site No. 1, the small scale of which made it in some respects the most difficult problem, and the third prize for Site No. 4, which was the most ambitious in scope. Mr. G. L. Morris was another architect to win a first prize (for Site No. 2).

SITE NO. 1.—FIRST PRIZE DESIGN BY A. TROYTE GRIFFITH.

SITE NO. 2.—FIRST PRIZE DESIGN BY GEORGE LL. MORRIS.

feature of the design is the way in which the kitchen window is shut off from the main garden, but, nevertheless, it is allowed a good view on to the broad border. Good use is made of the south side of the house for wall fruit, and the front garden is neat. The beds on each side of the approach path are, however, too small, and would doubtless be replaced in practice by borders about three feet wide.

In the first prize design for Site No. 2, Mr. George Ll. Morris has shown the clearest possible appreciation of the relation between the various parts of the house and the garden. The entrance forecourt is extremely simple, and relies upon plain paving and hedges. From the south side of it there is a little opening to a narrow private garden, with flower borders on either side of a path which leads to the main Rose garden. The trades entrance gives admission to a long path leading eastwards past the kitchen door to the vegetable

garden. From the dining-room there is a charming view across the Rose garden and sunk lawn to the distant herb garden, and from the drawing-room window an equally charming view is afforded under the pergola along a paved walk to the far pergola and arbour. The pleasure garden is divided from the orchard and kitchen garden by a long hedge with curved bays, which are on the axial lines of the lawn and herb garden and are pierced with entrances to them. The whole scheme is so contrived that there will be interesting views from all the important parts of the garden. The only criticism which need be made is the provision of stepping-stones across the sunk lawn. These are unnecessary, and would make an undesirable break in the pleasant surface of the turf. The use of Golden Privet for all hedges would tend to monotony.

Miss I. Grant Brown's design for Site No. 3 is also admirably contrived. The vegetable garden is placed in direct reference to the kitchen premises, and is divided from the pleasure garden by a

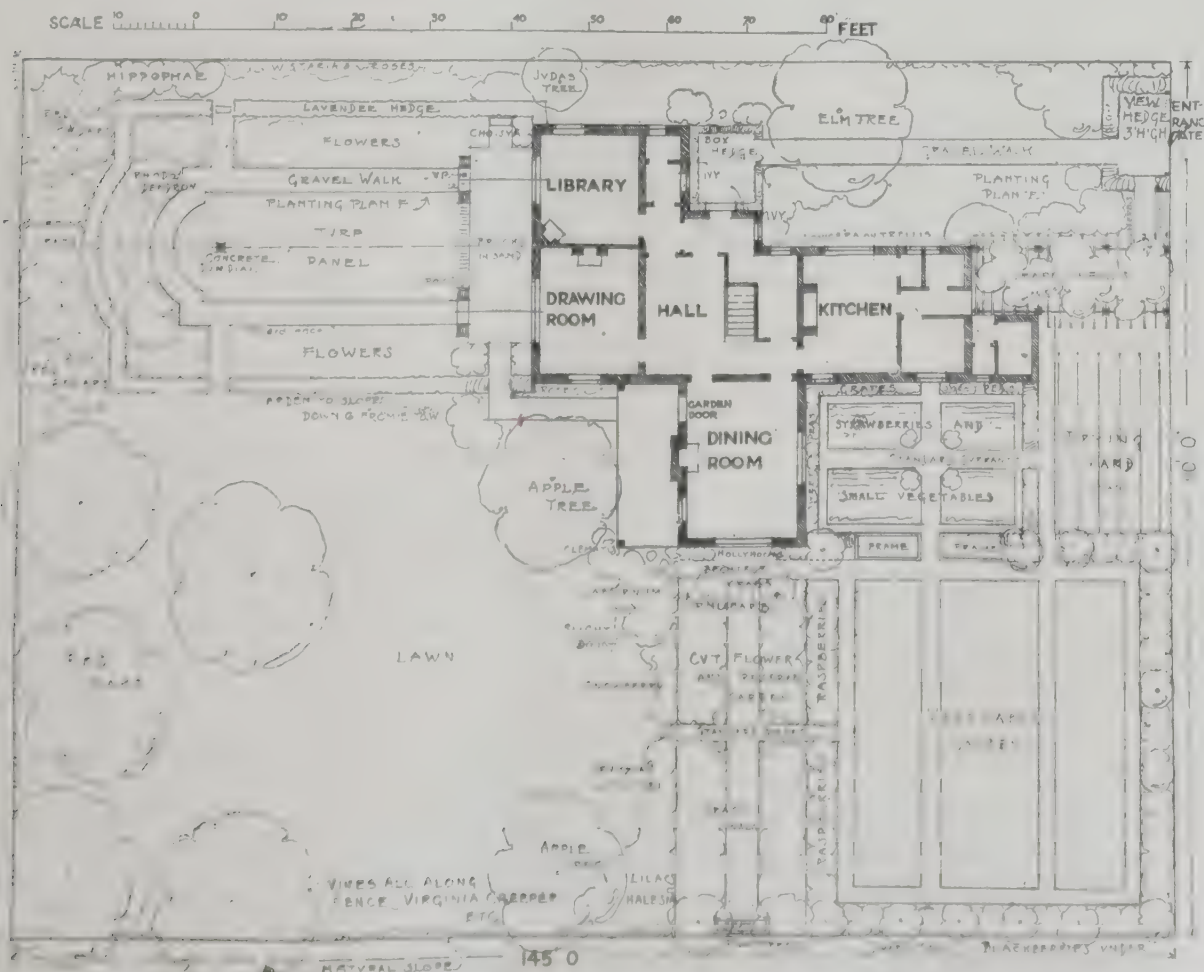

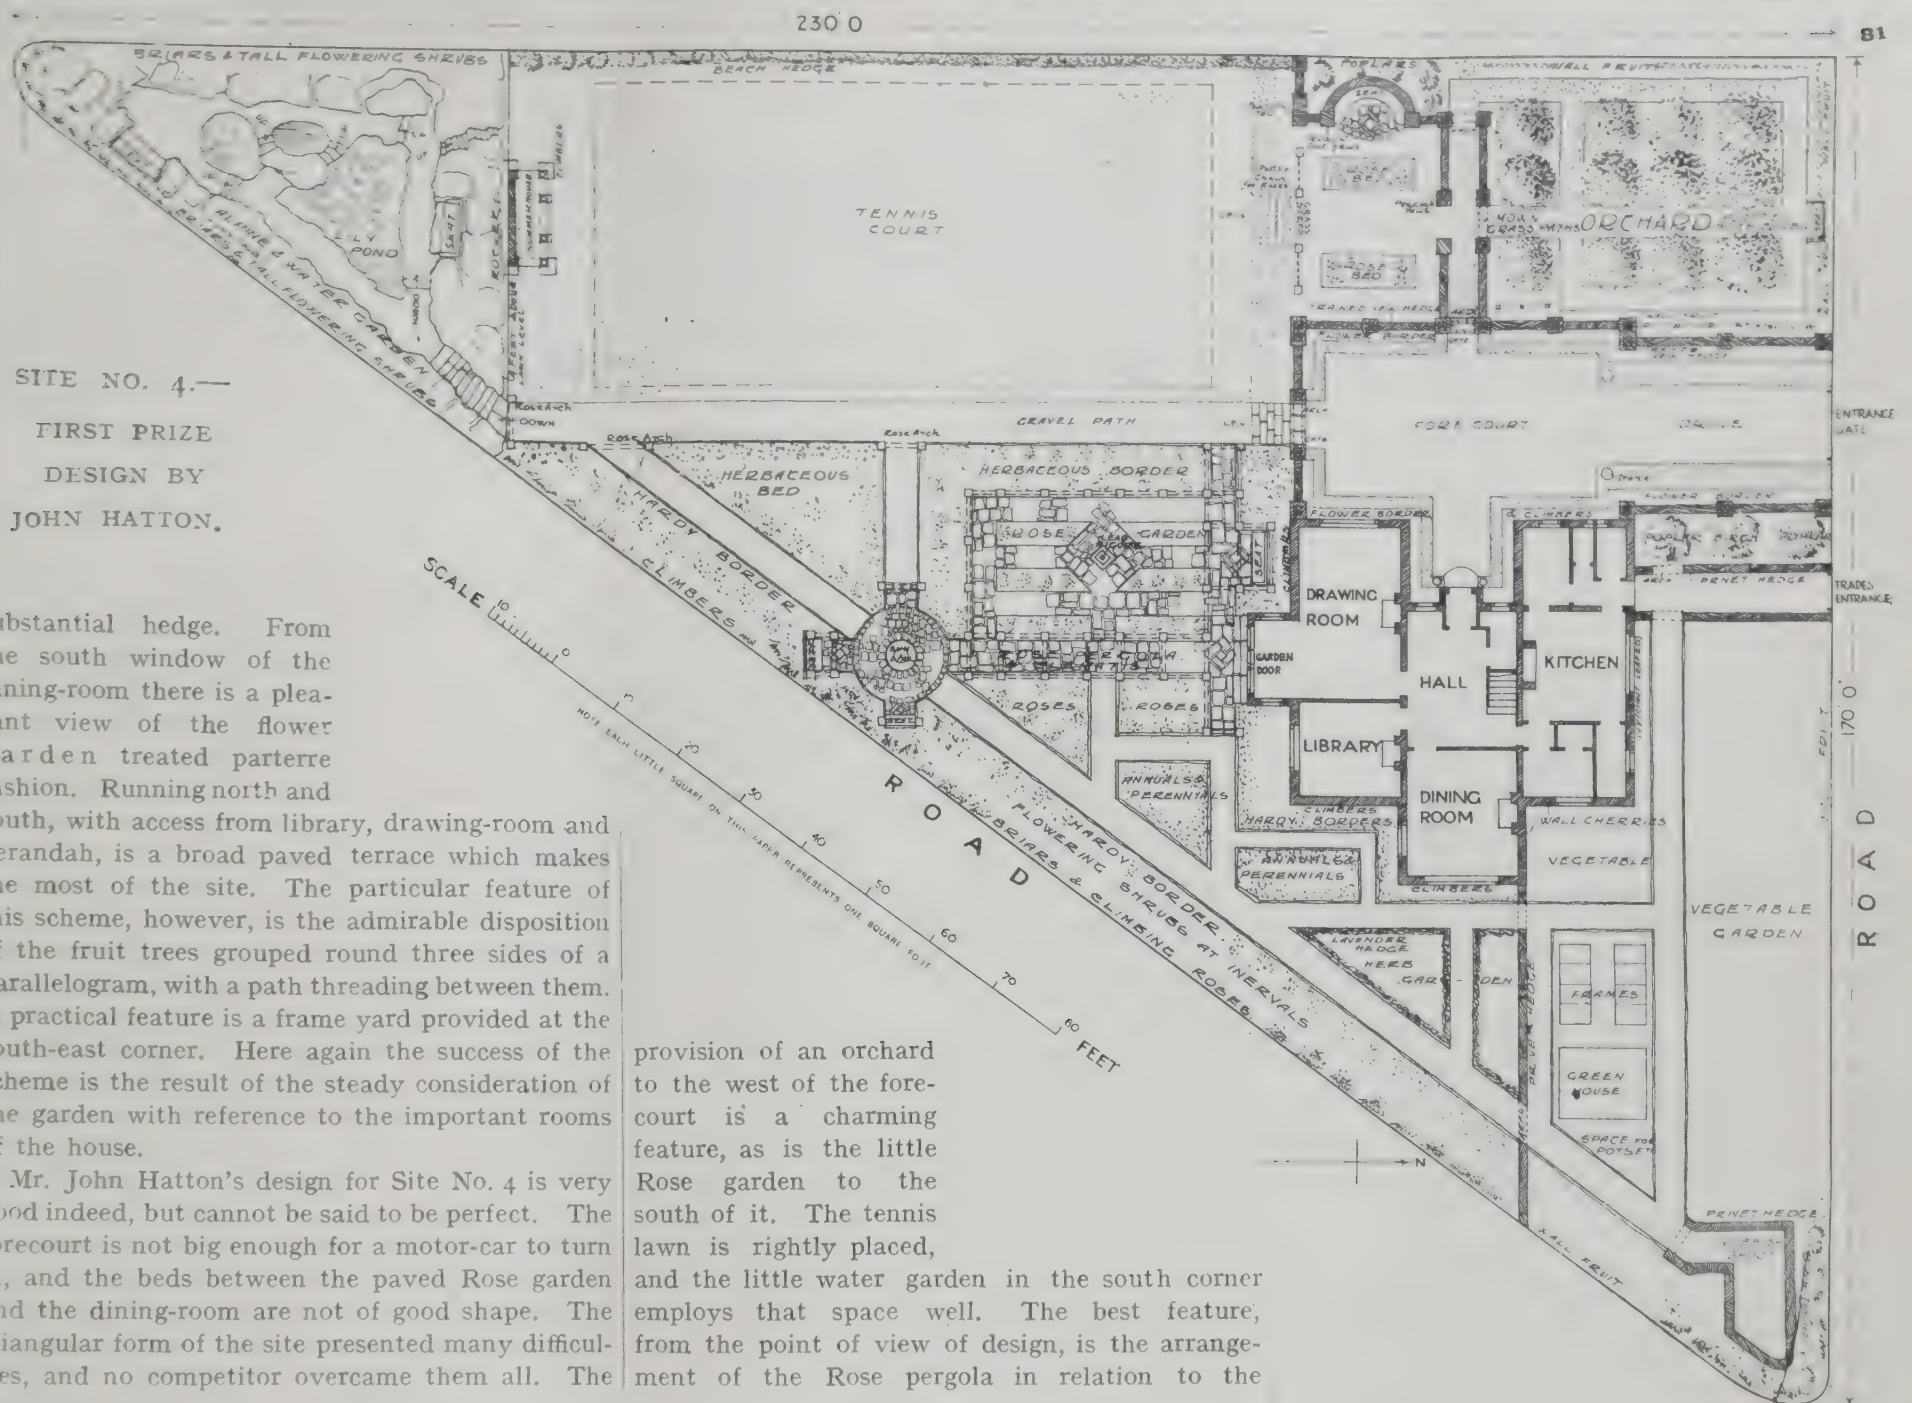

For the guidance of unsuccessful competitors, it is fair to say that their failure to secure prizes was due in the main to two defects of design—disregard of the relation between house and garden, and a lack of shapeliness in the various parts of the garden scheme. Some of them indulged in curling paths which meander aimlessly about the site and create shapeless and useless areas of grass or flower-bed. Others lacked a sense of scale, and provided long borders 2 feet or 3 feet wide or Rose plots no more than 2 feet square. Others placed what should be the more private areas of the gardens, where the owners would wish to sit, in full view of the road. Some neglected aspects altogether, and others paid no attention to the specified slope of ground. A few disregarded limits of cost, and showed features which would be appropriate only in a rich man's garden. It is proper to add here that the Judges did not allow themselves to be affected in the survey of the designs by the skill in draughtsmanship which some competitors showed, but made their awards with sole reference to the artistic and practical merits of the gardens themselves. Nevertheless, they were glad to note that the drawings were unexpectedly clear in their representation of the designers' ideas.

A few of the drawings were accompanied by very charming perspective sketches, and Mr. Kenneth Dalgliesh in particular is to be congratulated on the series he submitted, one of which is now reproduced.

I now pass to the first prize designs. Mr. Troyte Griffith's scheme for Site No. 1 achieved its place by reason of its simplicity and shapeliness. Perhaps the best feature of it is the splayed arrangement of hedges on either side of the drawing-room garden door. From this door there is a view straight across a simple grass plot to the semi-circular Yew hedge, with a good flower border on the north side backed by shrubs, and on the south side a border of Roses mingled with annuals. Two Apple trees make a pleasant background to the bottom hedge, and space is left alongside for a little plot for herbs or a frame. The cleverest

SITE NO. 3.—FIRST PRIZE DESIGN BY MISS I. GRANT BROWN.

garden door of the drawing-room, and there will be good vistas from the forecourt and also along the path running north-east and south-west. The vegetable garden and the rubbish shoot are well disposed in relation to the kitchen, and divided by a hedge from the pleasure garden.

We also illustrate the second prize design submitted by Miss Leonard (of Cambridge, Massachusetts) for Site No. 3. This is well and practically conceived, like all the plans which Miss Leonard submitted, and the Judges would have been able to give a higher award but for the unfortunate position accorded to the practical feature of a drying yard. In her design this is placed adjoining a road, and without anything to screen it from the public. Had it been cut off by a substantial trellis, there would have been no objection to this position, as a Grape Vine trellis and pergola screen it quite satisfactorily from the main entrance. It may well be that in the United States there is less squeamishness about the display of drying linen, but it would not be popular in this country. The vegetable garden and the flower garden are both practically conceived, and the lawn, dotted with Apple trees and red Oaks, would be a very friendly place to sit. This design shows a good compromise between the modern demand for rigid formality and the more haphazard disposition of features which makes the charm of so many old gardens.

LAWRENCE WEAVER.

THE LESSONS OF THE COMPETITION.

The problems set by the competition were by no means easy. They were, in effect, to compress within severely restricted areas an epitome of the art, principles and practice of garden creation. The plots selected for treatment were barren of anything that could assist in directing the mind toward any particular development, and it is with great pleasure that the Judges testify to the ingenuity and inventiveness displayed by many of the competitors in creating, out of such slight material, so much diversity of design and potentially picturesque effects. It is inevitable, after spending much time in consideration of the large number of plans submitted, and employing a process of elimination of the worst in order to choose the best, that the tendency of the Judges' comments is to become critical as regards all. We therefore devote our remarks chiefly to the lessons to be learnt from those points in which the various schemes fail, rather than from those in which they succeed.

One fact emerges from a consideration of such a number and variety of ideas as to what constitutes the best method of arranging a small garden, namely, that there were two classes of competitors who approached the matter from quite different standpoints. One class concentrated their efforts on an arrangement of paths, fences and a division of the area into spaces, each allotted for a specific purpose. Generally speaking, they failed to realise fully the fact that a garden is essentially a place wherein to grow things, and grow them in such a way that they shall fulfil Miss Jekyll's ideal, to "form beautiful pictures in our gardens." The danger in thus approaching the creation of a garden is that it attaches an infinite importance to the frame and ignores the picture. The tendency is to produce a garden which is a mere pattern, all design and no life, a stonemason's tombstone rather than a Pygmalion's Galatea.

The other class looked on the problem from the opposite standpoint, namely, that, given certain provision for growth and adequate planting schemes, little else mattered. These did not sufficiently realise that they had produced but a poor setting for their effects. In the result, whereas many plants may be well grown, they will never be seen to the best advantage, and in a small garden, in particular, a general sense of untidiness will always be in evidence.

PERSPECTIVE VIEW BY K. DALGLIESH.

The duty of the Judges, therefore, resolved itself largely into selecting those designs that most nearly attained to the ideal when judged from the standpoints the competitors had themselves taken. It will be seen from the published results that the balance was rather in favour of the first class. Due attention was, however, paid to the second, so that adequate provision was made in the selected plans for successful cultivation. It was felt that the making of the garden is in some respects more important than the planting, especially as the means of the owner were assumed to be limited. Obviously, if mistakes are made anywhere, a garden can be replanted with much greater ease and less expense than it can be remade. Judged on points, the planting schemes were inferior all round to the work produced in designing. This is regrettable but not surprising. It is far more difficult to produce satisfactory planting plans than a design based on certain principles, which, once grasped, reduce the task to an arrangement of lines and curves,

the effects of which are tested in the development of the plan on paper.

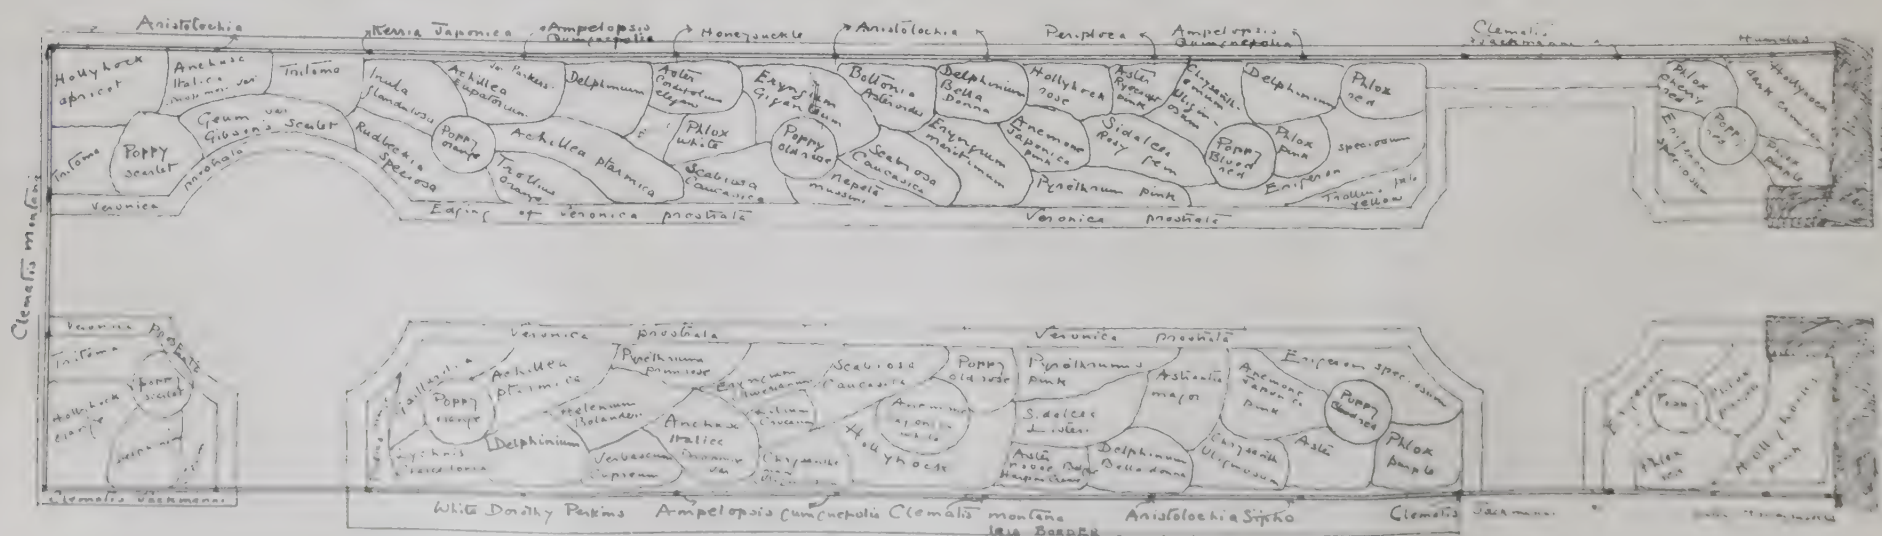

Consider for a moment the really excellent design produced by Mr. G. Ll. Morris for Site No. 2. It is easy to imagine some delightful effects in a garden arranged on these lines, but it would have been interesting to know exactly what he suggests should be planted in a herb garden to which as much space is devoted and into which as much design is introduced as for the Rose garden in the same plan. His vision of this little garden, with its seat placed to command a view down through the orchard, where flowering bulbs such as Crocuses, Tulips, Daffodils, Snowdrops, Scillas, &c., would doubtlessly be allowed to brighten the earth in spring, was really that of a garden of sweet-scented flowers and herbs, with Violets, Mignonette, Lavender, Lemon Verbena, Night-scented Stock and Tobacco Plant, each in their season creating an atmosphere redolent with garden perfumes. And then, Miss Leonard's borders seen from the drawing-room and library. If she had prepared her planting plans for these, they would have been masses of cool grey foliage with lavender, pale blue, the palest of yellow, cream and pink flowers, with perhaps a little dark purple used as a foil. They would have been planted principally with hardy perennial plants, with spaces left for spring bulbs, to be succeeded by annuals. An example of what plants Miss

Leonard would have used for this purpose would have been full of interest, especially as she would be considering the matter from the American point of view.

One planting plan by Miss I. Grant Brown (reproduced below) is in many ways excellent. She shows a full appreciation of the fact that it is better to group plants in relation to each other than to use them in serried lines or rigid blocks. Her colour arrangement is generally well thought out. Undoubtedly in the actual planting of these borders some provision would be made for prolonging the flowering period by introducing a few spring flowering bulbs and summer and autumn flowering annuals. The edging of *Veronica prostrata* is very neat when not in flower and brilliant when the flowering period arrives; an added interest would, however, follow a little more varied edging. There are innumerable dwarf plants that can be used for this purpose that have a longer flowering period.

GEORGE DILLISTONE.

F. W. HARVEY.

A PLANTING PLAN BY MISS I. GRANT BROWN.

PLANTING UNDER LARGE TREES.

IN the more prominent parts of the woodland, where the trees are surrounded with turf, it frequently happens that grass refuses to grow directly under the largest and most dense specimens. The result is bare, ugly patches that many experience some difficulty in clothing properly so that they harmonise with the turf. During recent years considerable attention has been given to the planting of these bare spaces with various kinds of low-growing shrubs. Some discretion is, however, needed in selecting shrubs for this purpose, because the majority of those which we would like to use refuse to grow in the dense shade which prevails during the summer months and the almost incessant drip from the branches of the overhanging trees during the winter.

Before any kind is planted it will be necessary to have the ground well prepared, and this is best done early in the autumn by digging it up thoroughly so that rain can soak in instead of running off the surface. In many instances the roots of the trees will be found quite close to the surface, but there need be no scruples about breaking a few of the smaller ones, as a healthy tree will always have an abundance of vigorous roots. Where there is very little loose soil present, and this obviously of a poor character, ten or more cartloads of good soil should be placed over the roots of each tree, so as to give the shrubs a start. When well established, the kinds mentioned later will thrive in almost any kind of soil and in dense shade. It is, however, most essential that well-rooted, sturdy plants be selected; weak specimens will most likely succumb the first summer. Should dry weather be experienced during the first year after planting, it will be necessary to give the shrubs good soakings of water at frequent intervals. So much depends on giving them a good start; a little special attention at the outset will be fully repaid in subsequent years.

Where a dwarf carpet of greenery is desired, there is nothing better than the common Ivy, and if plants are set out 18 inches to 2 feet apart and kept free from weeds the first year, a dense surface will soon be formed. Almost, if not quite, as good is the Periwinkle, a trailing semi-shrub of evergreen character. Another dwarf plant, of similar habit to the Periwinkle, is *Euonymus radicans*, which has dark green foliage, and where something extra choice is required, the variegated form of this may be used. All the foregoing may be kept dwarf, close and fresh-looking by annual clipping, this cutting to be done in March, just before new growth commences. If desired, odd bulbs of such strong-growing Daffodils as Emperor and Empress might be planted between the shrubs. They would give flowers for a few years until the shrubs became too dense. Another method of carpeting the ground under trees is shown in the accompanying illustration. Although it could not be carried out

where the trunks of the trees are large, it is very effective with trees of moderate dimensions. The Grape Hyacinths or *Muscaris* are charming little bulbous plants that produce their blue flowers in abundance in early spring, and if planted rather thickly beneath a tree, as shown, their grass-like foliage will make a green carpet for many weeks after the blossoms have faded. To get the best results the bulbs should be planted during the autumn, and then left alone for several years.

For taller undergrowth the common *Rhododendron ponticum* may be used in soil which does not contain an excess of lime; where decayed leaves are prevalent this *Rhododendron* is almost certain to thrive. A dwarf shrub that delights in similar soil is *Gaultheria Shallon*, and where desired this may be utilised for forming a broad edging to bold masses of *Rhododendron*. For very poor soils *Berberis Aquifolium*, *Aucuba*

GRAPE HYACINTHS OR MUSCARIS AS A CARPET. BULBS MAY BE PLANTED NOW.

japonica and the Oval-leaved Privet (*Ligustrum ovalifolium*) are all suitable. The *Berberis* can be kept to about eighteen inches in height by annual pruning, but the *Aucuba* and Privet will do better if allowed to grow 3 feet to 4 feet high. The common Butcher's Broom (*Ruscus aculeatus*) is a dwarf shrub, some two feet high, that will thrive under trees in most soils and localities. For carpeting the ground between trees that stand some distance apart, the St. John's Wort (*Hypericum calycinum*) is an ornamental and neat plant, and it has the merit of thriving in almost any kind of soil provided it is well drained. Any of the plants mentioned, when properly established, will look far neater and better than the worn, mossy scraps of turf that are too often found doing duty beneath trees. Good examples of undergrowth planting can always be seen at Kew, where considerable attention has been given to the subject.

L. L. M

THE AUTUMN TREATMENT OF LAND.

IN our issue for September 26 last we endeavoured to point out some of the fallacies that evidently exist about cultivating and cropping waste land. We also referred to an excellent leaflet (Special Leaflet No. 1) dealing with the subject that had recently been published by the Board of Agriculture. This is the most sensible advice that we have seen given during the present war, and through the courtesy of the Board we are able to publish it herewith. Of course, the advice relating to the sowing of crops in August is now too late for this year, but the tenor of the advice would be broken if this portion were omitted:

"The following suggestions and recommendations

have been prepared for the benefit of those who occupy small areas of land, such as allotments and gardens, or who wish to bring fresh land under spade cultivation with the view of increasing their supplies of vegetables during the coming autumn and winter and thereafter. It should, of course, be borne in mind that the suggestions made are dependent upon local conditions.

Land which is available for spade cultivation in small areas may be divided into three classes, viz.:

- (a) Land at present under spade or arable cultivation.
- (b) Good land which has been under permanent grass.
- (c) Derelict or waste land

CLASS A.—CULTIVATED LAND.

Assuming that land of this character has been well dug over and is in good heart, very little additional cultivation will be required in the autumn. The ground should, however, be dug

one spit deep, and a dressing of stable manure should be incorporated if the ground was not manured in spring.

For Sowing in August.—On such land the following crops might be sown immediately :

1. Early Turnips .. White and Purple Milan.
2. Carrots Early Horn.
3. Onions White Lisbon.
4. Lettuce Winter varieties.
5. Radish French Breakfast.
6. Spinach Winter or Prickly.

Seed should be sown at the following rates :

1. Turnips.—Sow 1oz. to 200 feet of drill half an inch deep. The drills should be 12 inches apart. Thin out to 5 inches to 9 inches apart according to variety.

2. Carrots.—Sow 1oz. to 300 feet of drill three-quarters of an inch to 1 inch in depth. The drills should be 12 inches apart. Thin out gradually to 5 inches, 6 inches or 8 inches apart according to season and variety.

3. Onions.—Sow 1oz. to 200 feet of drill (10lb. per acre) 1 inch deep. There should be 9 inches to 12 inches between the drills. Autumn-sown varieties need not be thinned.

4. Lettuce.—Sow half an ounce to 160 feet of drill a quarter of an inch deep, in rows 9 to 12 inches apart. Thin out or plant out, leaving 6 inches to 8 inches between the plants according to variety.

5. Radish.—Sow 1oz. of seed to 75 feet of drill 1 inch in depth, in rows 6 inches to 9 inches apart.

6. Spinach.—Sow 1oz. of seed to 65 feet of drill about one inch deep, in rows 12 inches to 15 inches apart.

For Planting Before Mid-September.—The following vegetables might be planted in August or early September :

1. Early Cabbage .. Any early variety.
2. Broccoli Winter and spring varieties.
3. Borecole or Kale.. Winter and spring varieties.
4. Leeks Musselburgh

They should be planted in the following way, viz. :

1. Early Cabbage.—Plant in rows, leaving 15 inches between the plants and 18 inches between the rows. Very dwarf varieties, however, succeed if only 12 inches is left between the plants and 15 inches between the rows. Strong-growing late varieties require 18 inches between the plants and 27 inches between the rows. The plants must be earthed up with a plough or hoe as the crop grows.

2. Broccoli.—Plant in rows, leaving 18 inches between the plants and 27 inches between the rows. The crop should be earthed up as in the case of Cabbage.

3. Borecole or Kale.—Plant in rows the same as Broccoli.

4. Leeks.—Plant in rows, leaving 4 inches to 6 inches between the plants and 1 foot to 15 inches between the rows.

For Sowing or Planting in October and Early November.—The following vegetables might be

sown or planted in October or the beginning of November :

1. Broad Beans.
2. Early Peas.
3. All varieties of Cabbage and Kale raised from seed sown in July or August. (Note.—If Cabbage and Kale plants are required for distribution on a large scale in October, seed should be sown in August at the rate of about twenty-five pounds per acre ; seed-beds of one acre should furnish about five hundred thousand plants.)

These plants will yield crops in the following spring and early summer, but too late to allow of Potatoes being successfully planted after them. They could, however, be succeeded by Onions,

FLOWERS OF THE NEW CREAMY WHITE COLLARETTE DAHLIA CANOPUS (MUCH REDUCED).

Broccoli, Brussels Sprouts, Kale or Carrots. Growers should remember that it is inadvisable that one crop of the Cabbage family should be succeeded by another of the same kind. Beans and Peas should be followed by Cabbage, and Cabbage by Onions, Carrots, or some kind of crop other than the Cabbage tribe.

(To be continued.)

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Laelio-Cattleya Mrs. Evelyn Norrie.—A very handsome bigeneric hybrid, in which the sepals and petals are clear chrome yellow, the crimson lip, heavily veined with white, having the frontal

lobe of deep crimson. A very beautiful and striking novelty.

Cattleya Princess Royal (C. Fabia × C. hardyana).—In this beautiful form the sepals and petals are rosy purple, the broad frontal lobe of rich crimson, stained and suffused with orange in the throat.

Cattleya Rhoda Fowler's Variety.—A form of much beauty and excellence. The sepals and petals are of rose cerise colouring, the lip of rich dark purple.

AWARDS OF MERIT.

Cattleya Antiope Brackenhurst Variety (C. chamberlainiana × C. aurea).—Sepals and petals light golden yellow, the moderately large, heavily

fringed lip having a broad frontal lobe of brownish velvet hue, the tube heavily lined internally. The foregoing four varieties named were exhibited by J. Gurney Fowler, Esq., Brackenhurst, Pembury, Kent.

Laelio-Cattleya Britannia Melanie.—In this distinct and handsome variety the pure white sepals and petals are of exceptional size and length, and ovate-acuminate in outline. The frontal lobe of the lip is of rich purplish crimson, in striking contrast to the wire-edged margin of purest white. From Messrs. Charlesworth and Co., Hayward's Heath.

Carnation Princess Dagmar.—A very handsome perpetual-flowering variety, having the rich velvety crimson colouring and fragrance of the Old Clove wedded to a flower of goodly proportions and fine build. The variety has the deeply serrated petals of many of the American class, the flowers well supported on stiff stems. It will doubtless receive a warm welcome for its fragrance alone. Shown by Messrs. Allwood Brothers, Hayward's Heath, and Stuart Low and Co., Bush Hill Park, Enfield.

Dahlia Canopus (Collarette).—The largest white-flowered variety of its class to-day and a variety of merit. The colour is creamy, not the chaste pure white of Eden, recently certificated. From Messrs. Stredwick and Son, St. Leonards.

Aster Purple Prince.—This is one of the Novæ Angliæ set and a seedling from Mrs. Bowman, upon which it is a great improvement, both in size and colour. The latter is of reddish purple hue, in fine contrast to the orange disc characteristic of many of its set. Shown by the Hon. Vicary Gibbs, Elstree.

Aster Cloudy Blue.—A good addition to the semi-double varieties, which have become so popular of late. The variety has a fine pyramidal habit of growth, freely set with flowers of pale lavender blue colouring of considerable size. It is said to attain to 3½ feet high. From Mr. Ernest Ballard, Old Court, Colwall, near Malvern.

All the foregoing were shown before the Royal Horticultural Society on the 6th inst., when the awards were made.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Strawberry Plants for early forcing should be fully exposed to light and air in order to ripen the crowns before the time arrives for placing them in their winter quarters. No hard-and-fast rule can be laid down with regard to time in this matter, as so much depends on the weather; but while open weather lasts, the best place for them is undoubtedly where they are. Keep the pots quite free from weeds and attend regularly to watering. Pots which are well filled with roots should be watered twice weekly with liquid manure from the farm-yard. When the time arrives for plunging the pots, there is nothing better than a bed of sifted ashes, which should be of sufficient depth to allow a bed 3 inches deep under the pots, as a protection from worms. If cold frames are available, the first batch of plants may be placed under cover in November, so that the soil may not become saturated with cold rain.

Tomatoes.—Plants from which supplies are being gathered will require very careful attention with regard to watering and airing. The house should not be quite closed while mild weather lasts, and during the day the ventilators should be fully open. Manure must be very sparingly applied to plants at this stage, but clear water must be freely given to the roots when necessary. Keep the plants within bounds by frequently stopping and thinning the shoots, so that no great quantity of growth is removed at one time.

Young Tomato Plants for early spring supplies ought now to be ready for potting into 3-inch pots. They should be placed quite close to the roof glass in a temperature of 55°. Water sparingly, and allow sufficient air to keep the plants from becoming drawn. The soil should consist of two-thirds turfy loam and the remainder of leaf-soil, with a good sprinkling of fine lime rubble.

Plants Under Glass.

Lily of the Valley.—A supply of this favourite flower may easily be kept up during the winter; and where sufficient fire-heat is available, the flowers may be produced in a very short time. When the crowns have been potted up, a covering of damp moss may be placed over them and kept moist by the frequent use of the syringe. Keep the soil moist and protect from strong light. Fresh batches of crowns should be placed in heat at intervals of ten days.

Cinerarias.—These should now be removed from their summer quarters and placed in pits with a south aspect. The plants will grow much better on a bed of ashes than on wooden stages. Keep a look-out for aphides, and fumigate the pit as soon as they appear. When the pots are well filled with roots, manure water ought to be frequently given.

Zonal Pelargoniums.—Plants for winter blooming should now be removed from cold pits to some well-ventilated structure where they can be placed within 2 feet of the glass, and where a little fire-heat can be applied during dull weather to keep the atmosphere of the house dry. The plants will benefit by frequent light dressings of some approved artificial manure.

The Hardy Fruit Garden.

Young Strawberry Plantations, made a month or two ago, will require careful attention with regard to water. Each plant must be examined and sufficient water given to keep the ball of soil in a moist condition; for if once allowed to become dry at this period, the result will never be satisfactory. The Dutch hoe should be frequently used among these young plants to keep small weeds in check.

Late-Fruiting Strawberries.—St. Antoine de Padoue is the best autumn-fruiting variety, and now is the time to propagate young stock for next season's crop. The runners should be removed from the old plants and inserted in small pots of rich soil. If placed in a close cold frame they will soon make roots, and the plants will benefit by the protection of the frame during the winter.

They will then make good plants for new plantations in March. A well-prepared north border should be selected for them, and, as the plants do not grow large, 18 inches between the rows will be sufficient, while a space of 1 foot will be necessary between the plants in the row.

The Flower Garden.

Herbaceous Borders.—The present is a good time for lifting, dividing and replanting the various subjects in the herbaceous borders; but before the plants are disturbed they should be carefully labelled. They may then be lifted and placed temporarily in a border near at hand while the ground is being trenched and prepared for them; and as this work proceeds, a good quantity of decayed manure should be incorporated with the soil. Wood ashes and old lime rubble may be freely mixed with heavy soil, while river sand may also be applied with advantage. When the ground is sufficiently settled, planting may be commenced; but previous to this the border should be marked out and the position of the most important subjects indicated, to avoid confusion. The height of the various plants, the colour of the flowers and the season of blooming must all be taken into consideration. When dividing the roots the best method is to pull them apart, and not cut them with a spade or knife. The pieces should be planted firmly, and the surface of the ground regulated as the work proceeds.

The Kitchen Garden.

Turnips.—The recent dry weather has been unfavourable to this crop, and sowings made for spring supplies should receive a good soaking of clear water, after which a sprinkling of artificial manure may be applied and lightly washed into the soil. These Turnips may be allowed to remain in the ground throughout the winter.

Celery.—The earthing-up of this crop should be accomplished as quickly as possible. Water the beds thoroughly a day or two before the soil is placed in position, remove all side growths, and tie up the foliage so that it may not be injured by coming in contact with the soil.

Lettuce.—A sowing should be made in a cold pit to produce plants to stand the winter under glass and for planting in the open garden in March with a view to cutting in May. Maximum is one of the best for this purpose.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Asparagus.—As soon as the tops change colour, the plants should be cut over, and the cuttings, as well as all weeds and rubbish, be carefully raked off. When the beds have been made tidy, a small mulch of some well-rotted manure may be given to protect the crowns during severe weather.

Tomatoes.—All the fruits from plants growing outside should now be cut and strung up to the wires in a vinery or Peach-house. These will all ripen in time, and if some are not quite fit for salads, they will at least come in handy for soups.

Rhubarb.—As soon as the growths of one or other of the early varieties have died down, a start should be made for securing a few roots for early forcing. Dig up one or two roots, according to requirements, and leave these on the surface exposed to the weather for a time; a few degrees of frost will give them the necessary check to render them fit for forcing. Continue to throw out a few roots at intervals to keep up a succession.

The Flower Garden.

Wallflower and Myosotis.—The planting of these spring-flowering subjects, if not already attended to, should be proceeded with at once. It must be remembered that the better the plants are established now, the better they will withstand

severe weather during winter. If by any chance the soil is dry, they should be given a good watering to settle the soil about the roots.

Hollyhocks.—In many districts it is quite safe to let these plants remain outside during the winter. Even here we never disturb them, and scarcely ever lose a plant. But as the soil and situation, more than frost, play a great part in this, it would not be advisable in all cases to follow this practice. When the soil is inclined to be of a retentive nature, it will be safer to lift them and winter them in cold frames. When the flower-spikes have faded, they will be quite ready to be moved. If, however, there is the least trace of freshness in the weather, this work had better be deferred for a time.

Top-Dressing Tennis and Croquet Lawns.—Now that the season is at an end so far as these outside games are concerned, the weeding and repairing of the turf ought to be attended to. In the case of weeds, the lawn should be gone over systematically, and Daisies, Plantains and other coarse weeds carefully taken up. In the case of hand weeding, mark off the lawn into sections of 3 feet or 4 feet, as, by so doing, no part of the lawn will be omitted. When this work is finished, top-dress the surface with a mixture of sifted soil or sand, adding a little approved lawn manure. This can be evenly distributed with a broom or the back of a rake. Where any turfing has to be done, the sooner this work is completed the better chance will it have to become knitted together before the close of the growing season.

Plants Under Glass.

Pot Roses.—Those intended for indoor culture should be looked over, and where repotting is necessary, this should be attended to at once. Have the pots thoroughly washed outside and in, and see that ample drainage is provided. A suitable compost would be loam inclined to be of a heavy nature, lime rubble and a sprinkling of bone-meal. Plants that do not require to be repotted must have the drainage examined and be top-dressed with the compost, as advised for potting. Plunge the pots up to their rims in ashes behind a wall, when they can be taken indoors as required.

Pelargoniums.—Those intended for winter flowering must now be placed in a greenhouse, and all flowers should be allowed to develop. Water must be given sparingly, and although air should be admitted freely on all favourable occasions, the atmosphere must be kept dry. A number of the older plants that have been flowering during the summer should be retained. They must, of course, be cut back, placed on a shelf and given little or no water. These will make good specimen plants for next season.

Retarded Lily of the Valley.—These crowns can now be obtained for forcing, and may be had in flower roughly from three to four weeks from the time they are potted. Unfortunately, although their culture is so simple, they are not always seen at their best. Many people rush them into heat the moment they are received. Now this is a great mistake. Place twelve to fifteen crowns in a 6-inch pot, leaving them well above the surface, and stand them in a cold frame for at least four or five days, covering the glass with a garden mat, by which time they will have grown 2 inches. They may then be transferred to the forcing-pit, and on no account allow the soil to become dry. Always water with tepid water.

The Hardy Fruit Garden.

Gooseberries.—Where a new plantation of these is intended, no time should be lost in preparing the ground, and as these bushes will, in the ordinary course of things, remain on the same ground for many years, the trenching of the ground must be done thoroughly. It is a great mistake to retain old, worn-out bushes, which are in most cases simply a harbour for insects, and at best only produce a moderate crop of under-sized berries; whereas these young bushes can be fruited the second year. Indeed, many of them will fruit the following summer.

JOHN HIGHGATE.

Hopetoun Gardens, South Queensferry, N.B.

ANSWERS TO CORRESPONDENTS.

TREES AND SHRUBS.

SMALL EVERGREEN TREE (G. A.).—It is possible that *Picea pungens glauca* will suit your purpose, although if a conifer other than a Fir or Spruce would do, you might try *Cupressus lawsoniana erecta viridis*. The former is a very beautiful tree, but has not such a good constitution as the latter. A hole 5 feet or 6 feet in diameter should be made and filled with good soil containing leaf-mould. October would be a better time for planting than November.

HOLLIES TURNING BROWN (K. M. S.).—It is not possible to say why your Hollies are turning brown without inspecting the plants, but as you say there has been a fire near by, it is possible that the flames have scorched the leaves. If the wet ground you mention is the cause of the trouble, you will find decayed roots. By digging a hole near the bushes you can easily discover whether there is any root trouble. The only way to get rid of water-rats is to shoot, trap, or infect them with Danyz Virus.

USE OF PEAT MOSS LITTER FOR RHODODENDRONS (L. A.).—Peat moss litter may be used as a surface-dressing for Rhododendrons, providing it is well decayed and is not used too lavishly. It is really a more satisfactory manure used as a surface-dressing than for digging in, although some people have found it satisfactory when used as an ordinary manure. A good deal of correspondence took place last spring in our pages as to the use of peat moss litter as a manure. It is now too late to prune Rhododendrons. Such severe pruning as you suggest should be accomplished in April, for then there is the full growing season to be looked forward to. If the plants were cut back at the present time, they would look ugly throughout the winter and spring, and the old branches would be less liable to produce new shoots than if the pruning were left until April.

FRUIT GARDEN.

BOTTLING PEARS (A. B. W.).—Unquestionably your failure is due chiefly to the fruit being too ripe. There is no reason why you should not be equally as successful with these as with the Plums. The bottling should take place as soon as the fruits have reached their full size and just before they commence to ripen. Sugar may be added at the time of bottling according to taste, and will often bring out the flavour of the Pears better than if done in pure water only. Some place two Cloves in each bottle and a little Lemon peel. All of the varieties named are suitable, but for preference select *Beurré Clairgeau*.

MISCELLANEOUS.

GRUBS ON PELARGONIUMS (E. S. H. S.).—We think your best plan will be to spray the Pelargoniums with lead arsenate next year if the grubs appear. You do not send any, but from what you say we suspect your plants are attacked by the larvæ of the silver Y moth.

HOUSE DRAINAGE (H. H., Cheshire).—If the tank is the receptacle of nothing stronger than sink or bath water, or these with rain-water, the Rose-beds may be freely watered through the growing season once or twice weekly with advantage. If cesspool matter is mingled with these, the liquid might be given once a fortnight during the same period, and once a month at other times. The question is one which can hardly be satisfactorily answered with the information before us.

EFFECT OF TARRED ROAD ON PLANTS (Dun Spiro, Spero).—We can hardly think the tar of the road would have the evil effects you speak of, and especially so far removed as some of the plants are from the tarred area. It is very difficult to say exactly what may have been the causes without seeing the plants, but all the symptoms that you speak of may very well have been produced through lack of water at a critical time, and we are inclined to think the extraordinary weather we have experienced this season is to blame.

POT-POURRI: THE DRY PROCESS (E. J.).—Pink Roses, when they are thoroughly dry, should have the petals pulled apart, laying them thinly on sheets of paper in an airy room till they are quite dry. Sweet Geranium leaves and Lavender are also dried, the larger kinds of Geranium leaves being pulled to pieces. For a quantity equal to two-thirds of a bushel, have the following spices and gums, all in powder or finely crushed: Cloves, mace, and cinnamon, 2oz. of each; coriander, allspice, gum styrax and gum benzoin, half an ounce each; violet powder, quarter of a pound. Mix all well together. There is a whole chapter on the making of pot-pourri, with a detailed description of the moist process—a process that cannot be described in a few sentences—in Miss Jekyll's book, "Home and Gardens" (Longmans).

NAMES OF PLANTS.—J. J.—The plant you send is the Thorn Apple (*Datura Stramonium*). It is really a weed.—*Mrs. A. Thomson.*—We think the Rose is Lady Hillingdon or possibly Marquise de Sinety; it is impossible to name so dried a specimen with any certainty.—*F. A. Sturge.*—*Crocus nudiflorus.*—*Alfred Allhusen.*—*A. Charleis heterophylla*; *B. Spirea japonica*; *C. Liatris graminifolia.*—*F. Marples.*—1, *Linaria maroccana*; 2, *Teucrium Botrys*, a rare British plant.—*Thomas Bicknell.*—The Pink is a form of *Dianthus Sequieri*, probably a hybrid of it and some other species.

NAMES OF FRUIT.—W. S. Tillett.—Crimson Costard.—*H. B. B.*—1, Charles Ross; 2, New Hawthornden; 3, Blenheim Orange; 4, Cornish Aromatic; 5, Winter Peach; 6, Cox's Orange Pippin; 7, Rosemary Russet; 8, Pickering's Seedling; 9, Sugar Loaf; 10, Reinette Grise; 11, King of the Pippins; 12, Rambour Frone.—*J. M., Barn Green.*—1, Stirling Castle; 2, The Queen; 3, Bismarck; 4, Newton Wonder; 5, Cellini Pippin; 6, Fearn's Pippin; 7, Cox's Pomona; 8, Beurré Dumont; 9, Princess.—*W. Cann.*—American Mother.—*John Gibbins.*—Beurré d'Anjou.—*W. Lumley.*—1, Norfolk Beauty; 2 and 5, Golden Spire; 3, Christmas Pearmain; 4, Lord Grosvenor.

OBITUARY.

JOHN GOULD VEITCH.

It is with regret that we have to announce the death of Mr. John Gould Veitch, of the well-known firm of Messrs. J. Veitch and Sons, which occurred on the 3rd inst. The deceased, who was only forty-five years of age, was the only surviving son of the late John Gould Veitch and a nephew of Sir Harry J. Veitch. He was an M.A. (Cambridge), and also took his Blue, being an expert at football. He took an active part in the Chelsea business, but of late years, owing to failing health, was not able to appear much in public. He leaves a widow and one child, to whom we tender our deepest sympathy in their sad loss. The funeral took place at Putney Vale Cemetery on the 7th inst. amid many tokens of the esteem in which he was held.

SOCIETIES.

BIRMINGHAM AND MIDLAND COUNTIES GARDENERS' ASSOCIATION.

A LECTURE on "The Border Carnation: Its History and Cultivation" was given at the opening of the autumn session on Monday, October 5, by Mr. A. R. Brown of King's Norton. The last meeting's minutes having been read, Mr. Herbert (chairman) called upon the lecturer, stating that Mr. Brown's experience with this plant had made him familiar with much respecting its cultivation, and the advice he was able to give was invaluable to growers. The history of the Carnation, said the lecturer, dates back to 300 B.C., when it was described by Theophrates, the ancient botanist, in whose hands botany attained its highest development. It was he who endowed this plant with its generic name, *Dianthus*, i.e., Divine Flower, and for a long time it was cultivated only in its relation to medicine and cookery. Pliny also informs us that the Romans used it for sops in wine and ale, as it imparted thereto a spicy flavour. To Chaucer, in the reign of Edward III., could be traced the first mention of its cultivation in England, while, later on, in Shakespeare's famous writings it came in twice. During the intervening ages until to-day, the literal meaning of Carnation had slightly altered, like the word *Picotée*, derived from the French *picoté*, meaning spotted—a mere misnomer at the present day—for the chief point in the *Picotée* at present is its purity, spots or bars being grave defects. At one time the split calyxed "burstlers" were alone preserved for cultivation, "whole blowers" not being deemed worthy of any serious attention until 1740, when they ousted the coarser varieties. At this time, too, serrated petals became regarded as a serious blemish, and accordingly were eliminated. More than sixty years ago the present standard of excellence for Carnations was arrived at, and since then it has remained unaltered. Towards the nineteenth century, bizzarres, flakes and white-ground *Picotées* became the valued varieties, selfs then being termed as "wasters"; but in the thirty-five years which have elapsed since the marvellous improvements by several gentlemen revolutionised this flower, the once despised selfs have become the most popular type of this "Divine of Flowers." Mr. Brown next proceeded to give a few cultural notes, detailing the method of his own procedure through all the numerous stages, from the time of propagation to the flowering time of the plant. He also dealt with lists of the best of present-day varieties, gave some useful suggestions for the benefit of intending exhibitors for the future, and ended his discourse with some further remarks on the Carnation in the border. The lecture, which was of a highly interesting nature, full of excellent information, was thoroughly enjoyed by all. The meeting concluded with a well-applauded vote of thanks proposed by Mr. Cryer and seconded by Mr. Higley. Before the close, the secretary (Mr. Deedman) made reference to a box. This had been requisitioned for fortnightly voluntary contributions of the members for the benefit of the Prince of Wales's Fund. A member, Mr. Farmer, had with great generosity provided, as an initial donation, £1, and this, together with the first evening's contributions, now made up a total for the purpose of the Fund of £1 10s. 6d.

ROYAL HORTICULTURAL SOCIETY.

AT quite short notice, and in large degree unexpected, quite a creditable exhibition was brought together on the 6th inst. at the Royal Horticultural Society's Hall, Vincent Square, a considerable number of Fellows visiting the show in the afternoon. An outstanding feature of the meeting was the superb collection of fruits—Apples and Pears—from Eynsford, than which nothing finer has been exhibited. From Weybridge came a very creditable lot of Pears, albeit the district is not well suited to fruit culture. Considerable interest, too, attached to a hybrid set of Marrows, of which doubtless more will be heard in the future. The commercially grown Crotons from Edmonton were of a high order of merit. Hardy plants were well represented, Michaelmas Daisies being very fine. Sprays of cut trees and shrubs demonstrated the high leaf ornament of these at this season. No Orchid groups were staged, though five important new Orchids gained awards. The floral committee granted awards to four novelties. For descriptions of these see "New and Rare Plants," page 512.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. R. C. Notcutt, R. Hooper Pearson, J. Green, E. A. Bowles, W. J. Bean, G. Reuthe, C. B. Fielder, F. W. Harvey, J. W. Moorman, J. Dickson, H. J. Jones, A. Turner, C. E. Pearson, W. P. Thomson, E. H. Jenkins, J. W. Barr and James Hudson.

The magnificent group of Roses set up by Mr. G. Prince, Oxford, attracted much attention by reason of its variety and excellence. For the month of October the flowers were charmingly fresh and good, while in not a few instances the normal or summer colour was distinctly heightened. Of the new Hybrid Tea *Josephine Nicholson* quite an imposing central group was staged, the fresh self pink colour showing to great advantage. Other excellent varieties were *Rayon d'Or* (deep yellow and in considerable quantity), *Lady Pirrie* (rich salmon), *Mrs. Herbert Stevens* (white), *Snow Queen* (the revised name of *Frau Karl Druschki*), *Liberty*, *Lady Hillingdon* and *Mrs. A. Tate*.

Messrs. H. J. Jones, Limited, Lewisham, S.E., showed a table of Michaelmas Daisies, for which a silver Flora medal was awarded. The group was admirably displayed, bold, effective, full-length sprays producing what is so much needed at exhibitions, viz., good garden effect. Prominent varieties were *Silver Queen*, *Don* (a fine clear blue), *Henri Adams* (deep blue), *Bianca*, *Lil Fardell* (rosy red), *Queen* (palest mauve), *Climax*, *White Climax*, *Sirius* (rose) and *Magnet* (clear blue).

Mr. W. Wells, jun., Merstham, showed herbaceous Phloxes, such as *Frau Ant. Buchner* (white), *America* (pink), *Le Mahdi* (blue), with *Asters Climax* and *cordifolius* Photograph, and *Erigeron Quakeress* (a rather delicate mauve-coloured kind characterised by great freedom of blossoming).

Messrs. J. Cheal and Sons, Crawley, had an exhibit of cut shrubs and trees valuable for foliage effects. Of these, *Crataegus prunifolia*, *Pyrus Aucuparia discolor* (very fine), *Prunus Moseri* fl.-pl., *Baccharis halimifolia*, *Amelanchier canadensis*, *Acer japonicum laciniatum* (very fine), *Tamarix hispida æstivalis* and *Kolreuteria paniculata* were some of the finest examples. Many species of Oak were also brilliantly coloured, the effect of the whole remarkable in the extreme.

The Misses Hopkins, Shepperton-on-Thames, showed a small collection of alpine. *Sedum pulchellum*, *Potentilla Tonguei*, *P. willmottiana*, *Tunica Saxifraga*, *Teucrium Polium aureum* and *Hypericum reptans* were interesting examples in flower.

Messrs. Allwood Brothers, Hayward's Heath, showed Carnations. *Salmon Enchantress*, *May Day*, *Wivelsfield White* and *Princess Dagmar* were some of the more important in a nice lot.

Messrs. G. and A. Clark, Limited, The Nurseries, Dover, showed *Helianthus sparsifolius*, *Armeria gigantea*, *Cimicifuga simplex*, *Zauschneria californica* and a variety of *Aster Amellus*.

Mr. C. Engelmann, Saffron Walden, showed Carnations, such as *White Wonder*, *Fanny* (fancy), *Mrs. C. F. Raphael*, *Sunstar* (yellow), *Carola*, *Scarlet Carola*, *White Enchantress*, *Lady Meyer* and *Lady Northcliffe*. *Circe* (heliotrope fancy) was very good. It is one of the most attractive of its class.

Mr. Amos Perry, Enfield, showed good hardy flowers, such as *Helianthus sparsifolius* (very fine), *Kniphofias*, *Senecio pulcher*, *Erigeron Amos Perry* (mauve), *Aster St. Egwin* (rose), *A. Amellus Distinction*, *Helenium autumnale rubrum*, *Kniphofia Macowanii* and *Armeria plantaginea gigantea*. *Dianthus Napoleon III.* was finely presented in flower.

Messrs. Barr and Sons, Covent Garden, showed Michaelmas Daisies, early-flowering *Chrysanthemums*, *Kniphofias* in variety, a delightful lot of hybrid *Nerines* and Autumn Crocuses, such as *C. pulchellus*, *C. speciosus*, *C. hadriaticus* (white), *C. saundersianus* (white) and *C. cancellatus albus* (white, lined with faint blue). Some *Gladioli* were also shown.

Mr. Ernest Ballard, Colwall, Herefordshire, showed a table of new Michaelmas Daisies, such as *Glory of Colwall*, *Mira*, *Peggy Ballard* (double blue), *Ragtime* (rosy mauve) and *Edith Goodwin* (fine blue). *Rosy Morn* was also pleasing and effective. *Cloudy Blue* (award of merit) is virtually a mauve blue counterpart of *Beauty of Colwall*. It is very charming.

Messrs. Stuart Low and Co., Enfield, showed Carnations *Yellow Prince*, *Baroness de Brienon*, *British Triumph*, *Snowstorm*, *Enchantress Supreme*, *White Enchantress*, *Satin Robe* and *Salmon King*. The new *Princess Dagmar*, crimson (see "New and Rare Plants"), was also noted.

THE GARDEN.

No. 2240.—VOL. LXXVIII.

OCTOBER 24, 1914.

NOTES OF THE WEEK.

Raiser of Rose Excelsa Honoured.—The Hubbard gold medal, offered by the American Rose Society for the best Rose of American origin introduced within five years, has been awarded to Mr. M. H. Walsh of Wood's Hole, Mass., for raising the rambler variety Excelsa. We have already had considerable experience of this fine crimson Rose in this country, and predict that it will, before many years have elapsed, oust Crimson Rambler from our gardens.

A Black Apple.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. I. A. Walker of Woodberry, Sydenham Hill, S.E., sent a perfectly black Apple. Only once before has an Apple having this appearance been shown before the committee, and on that occasion Dr. M. C. Cooke attributed the appearance to an attack of the fungus *Sclerotinia fructigena* (= *Monilia fructigena*), the cause of brown rot of various fruits.

Doronicums in Pots.—The Leopard's Bane is a well-known bedding and border plant; but it is not widely known that *Doronicum plantaginifolium*, taken up from the open ground and potted now, will flower well early in the new year if gently forced in a temperature of from 45° to 55° by night and 65° with the heat of the sun by day. Its value as a decorative plant in a cut state needs no recommending, and to get it at that time of the year would greatly increase its value, for its bright yellow flowers last fresh for a long time.

A Beautiful Climber for a Sunny Aspect.—*Tecoma grandiflora* is one of the most beautiful of climbers, and flowering as it does so late in the summer and autumn, it is particularly valuable. This year it has been flowering with exceptional freedom in many places, its terminal panicles of large, trumpet-shaped, orange scarlet flowers being very conspicuous. It should be planted against a south wall where it can get all the heat possible. Wood of the previous year should be cut back in the spring, but apart from this no other attention is required. It was introduced from China and Japan about 1800, but is not often seen. *T. radicans*, from North America, much resembles it, requiring a similar position and treatment.

An Interesting British Seashore Plant.—*Convolvulus Soldanella*, perhaps better known as *Calystegia Soldanella*, is among the few but distinct plants that constitute the flora of the coast sandhills. Next to the blue Sea Holly (*Eryngium maritimum*), this handsome Bindweed, with its large pink flowers, is most conspicuous, rambling among the curious formations of wind-blown sea sand, although

summer and early autumn. It is best raised from seeds sown early in autumn.

Buddleia Colvillei Flowering in October.—Messrs. R. Veitch and Sons of Exeter kindly send us a flowering spray of this handsome hardy shrub, with the intimation that it is now flowering in their Exeter nursery for the second time this year. It would be interesting to learn whether it is producing its second crop of rose pink flowers in other parts of the country.

A Beautiful Autumn-Flowering Shrub.—In our issue for October 10 we published a note on sprays of *Escallonia montevidensis* sent us by Mr. J. E. Sanders of Redruth. At the request of several readers we publish herewith an illustration of flowering sprays of this charming shrub, which is often known in gardens as *E. floribunda*. The blossoms are pure white, and at a little distance the inflorescences have the appearance of white Lilac. In the southern and western counties of England, and also on the west coast of Scotland, this shrub has proved hardy. In common with other members of its race, it appreciates well-drained soil that is rather on the sandy side, and if the garden is an exposed one it is safer to plant against a wall with a southern or western exposure. Late summer and autumn flowering shrubs are by no means plentiful, hence we ought to make full use of those that are available.

Shirley Poppies in October.—One of the most charming features in the gardens at Hampton Court just now is a colony of Shirley Poppies growing close by the famous vinery. These are in full flower and look as vigorous and healthy as we are accustomed to see them in July. Evidently the plants are the result of sowing seeds during June or July, a practice that might well be adopted with a number of other quick-

FLOWERING GROWTHS OF ESCALLONIA MONTEVIDENSIS. A BEAUTIFUL SHRUB FOR THE AUTUMN.

growing annuals. We record the feature now so that readers may make a note of it in their garden diaries for next year. While writing of the gardens at Hampton Court, it is interesting to note that the names *Aubrietia* and *Swainsona* are spelt wrongly on the labels there. The former has lost an "i" and the latter has gained one. It is a small matter, but one that ought to be remedied

it does not occur so frequently as the *Eryngium*. It is an interesting plant, as the stems run under the surface, and only the small, thick, fleshy leaves and large pink flowers rise above the bleached sand and enjoy the full power of the blazing sun. It will succeed quite well in our gardens if planted in sandy soil in full sun, and will be an object of beauty during

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Chrysanthemum Shows for the War.—I note in your recent issues that many Chrysanthemum shows are not to be held this year. No doubt the same number of blooms and plants have been grown this season, and no doubt, also, thousands of lovers of the Autumn Queen will be keenly disappointed at not being able to get a glimpse of some of them. I suggest, therefore, that growers (amateur and professional) might invite all and sundry to inspect their respective displays, making a charge of, say, sixpence, and, after defraying any incidental expenses, the balance might be sent to the War Relief Fund. Such as are willing to do this could send you their names and addresses for publication.—M. E. G., *Beckenham*. [We shall be pleased to publish the names and addresses of those who fall in with our correspondent's suggestion.—Ed.]

Cotoneaster horizontalis.—The bright scarlet fruits of this Cotoneaster are highly pleasing at the present time, but it will not be long before

uncommon for the white variety to fruit, but it requires a hot, dry season like the present or that of 1911 to bring the fruits to reasonable maturity. The tree here fruited in 1911, but I have never seen any fruits on the pink variety that we have. The size of the best fruits would be as large as Walnuts before the green hulls have been removed.—C. TURNER, *Ken View Garden, Highgate*.

When to Plant Tulips.—With regard to the Editor's note at the end of my paragraph on the above subject in *THE GARDEN* of October 10, page 490, expressing a desire to know how our late-planted Tulips behaved the following season, I regret to say that I have no record or recollection of this. Being a cheap variety, they would most likely be planted among a mixed lot, as I attached no great importance to the matter at the time.—CHARLES COMFORT.

—As a mild Tulip maniac I, naturally, have been interested in the correspondence relating to the above, more particularly with regard to late-flowering varieties, of which I grow a considerable number. So far as my own experience goes, it makes little or no difference whether Darwin and Cottage Tulips are planted early or late. At least the only difference I have

were shown in. I found they were M. Pernet-Ducher and his daughter and a representative of the *Daily Mail*. Mlle. Pernet-Ducher spoke excellent English, and stated the case on behalf of her father, who did not speak English freely. The point was, the *Daily Mail* people would like the new Rose Mme. Edouard Herriot—which the day before had been awarded their gold cup—named the *Daily Mail* Rose. I pointed out that no such condition attached to the offer of the cup in the schedule, and therefore it must be a matter of arrangement between M. Pernet-Ducher and the paper in question. The Directors of the "International" had no duty in the matter further than to carry out the judges' decision and present the cup to M. Pernet-Ducher. M. Pernet-Ducher explained why he could not name the Rose the *Daily Mail* Rose—"It had already been named after his dear friend, the Mayoress of Lyons." I suggested that the other side might be satisfied by putting "the *Daily Mail* Gold Cup Rose" in parentheses after the name Mme. Edouard Herriot. It was the only way out, and we smilingly shook hands all round.—W. CUTHBERTSON, *Edinburgh*.

An Interesting Exhibit of Hybrid Marrows.—At the Royal Horticultural Society's exhibition held at Vincent Square on the 6th inst., a group of hybrid Vegetable Marrows shown by Mr. F. Herbert Chapman of Rye, and the raiser of the now well-known yellow Freesia bearing his name, created considerable interest. At a time like the present, when the value of all kinds of home-grown food is appreciated, we think particulars of these Marrows will be of interest to our readers, and Mr. Chapman has kindly furnished us with the information given below. We understand that the whole of the collection has been sold to Messrs. James Carter and Co., so that the public will no doubt, in due course, be able to obtain seeds. The exhibit, illustrated herewith, received a silver-gilt Knightian medal, awarded by the unanimous vote of the fruit and vegetable committee. Mr. Chapman writes: "The series of Marrows exhibited by me at the Royal Horticultural Society's meeting all originated from a cross made several years back between the Custard Marrow and the variety Table Dainty, the former being the seed-bearing parent. Being always a believer in flavour in vegetables as opposed to size, it had often occurred to me that if the delicate and rich flavour of the Custard Marrow could be imparted to a fruit more amenable in shape to culinary uses, a point would be gained. All who have practised hybridising for some few years become aware that it is a game of surprises, but I was scarcely prepared for the number and variety of types which evolved from this one individual cross. Although almost all on the small side, yet the variations in shape, colour and marking are most pronounced and remarkable. Between fifty and sixty dishes were shown, and there were nearly that number of quite distinct types, ranging through all the shapes of the present commercial varieties, with the addition of fruits resembling a balloon, a Ridge Cucumber and other queer forms. In colour, too, they run from pale cream through all shades of green, striped and mottled, to a green which is almost black. In some the true Custard flavour is quite pronounced, and when the best types are selected and thoroughly fixed I am ambitious enough to hope that a useful addition will have been made to our none too long list of delicate and toothsome British vegetables."

THE INTERESTING COLLECTION OF HYBRID VEGETABLE MARROWS RAISED AND EXHIBITED BY MR. F. HERBERT CHAPMAN.

they fall to the ground, unless eaten by the birds. Self-sown seedlings frequently appear in my garden, some of them at a considerable distance from the parent plants, the produce, no doubt, of berries carried by the birds.—S. ARNOTT.

Crab Apple Jelly.—As Crab Apples are so plentiful this year, and are now ready for making into jelly, we are pleased to publish the following recipe kindly sent us by a lady correspondent: "To 9lb. of Crab Apples add 3 quarts of water. Boil the Apples until they go to a pulp. Then strain through a jelly bag, measure the juice, and allow three-quarters of a pound of sugar to each pint of juice. Add the sugar; then put into the pan and well boil for twenty minutes."

Fruiting of Double-Flowered Peach.—Neither of the correspondents who have written on this says whether he refers to the white or pink flowering Peach. We have a specimen of the former about eight feet high and six feet through which has had quite four dozen fruits (some still hanging), the bulk of which have been of quite an acceptable flavour. Besides being edible in the raw state, these fruits are very good when stewed, also for making tarts. It is not altogether

observed is that bulbs planted in December are a few days later in blooming than those planted in October or left in the ground from the previous season. Having such a number, I make a point of lifting about half my stock each year, so that all the bulbs have two seasons of blooming before being lifted. When left more than two years, the bulbs deteriorate somewhat, especially when grown in a herbaceous border or among Roses, as I am forced to grow mine. There certainly is no advantage in planting late-flowering Tulips before October, for even when left in the ground the bulbs do not start making root until October; in fact, I have recently lifted bulbs that did not show any signs of starting.—T. A. WESTON. [This failure to start is probably due to the excessive drought.—Ed.]

An Unreported Incident at the "International."—A *propos* the article in your issue for October 10 entitled "Rosa Pernetiana, 1838—1914," I am reminded of an interesting incident at the International Show. One morning—the morning after the awards had been made—I was on duty representing the Special Jury in the Directors' Room. Two gentlemen and a lady

ROOT PROPAGATION OF HARDY HERBACEOUS PERENNIALS.

NO phase of gardening is more fraught with interest than the general propagation of plants. That numbers of plants reproduce themselves a hundredfold by means of their roots is well known, and we have instances of this in mere weeds, as, *e.g.*, the Dock and the Dandelion, or in the garden in certain sections of the Michaelmas Daisy. In these directions, however, the knowledge we possess of these facts is of service in assisting to keep such rampant-growing plants within proper limits. But other plants display a marked tendency to reproduce their kind by means of roots, which, however, are of little value to the gardener for some reason or another. Of these the Heleniums and the Phloxes are instances, and as the plants are easily increased by cuttings or division in the usual way, their multiplication by any other means is neither desirable nor profitable. But there are other instances where root propagation is of much value, and particularly so in those cases where the plants, producing no cuttings in the usual way, are also difficult to increase by seeds or division of the roots. Now and again one meets with a plant which rarely produces a fertile seed in this country at all, and which is also almost impossible to increase by the ordinary methods of division. Such a plant is *Senecio pulcher*, an invaluable plant during the late summer and early autumn months, and one but rarely seen in good condition. Hence root propagation in such a case is of great value, and prevents so good a plant being lost to cultivation altogether.

From another point of view, root propagation is of great value to the specialist, as by its means selected examples of certain plants which cannot be relied upon to come true from seeds may be readily increased and always prove true to their kind; that is to say, while the flowers or seeds are exposed to cross-fertilisation by insects, the roots still retain the true character of the individual plant in its entirety.

Quite recently many of our readers have made enquiries into this method of plant propagation, and the subject being of a seasonable nature, we give in greater or less detail the essential items for its successful adoption. Happily for those interested, the work may be carried out during the winter season, and, indeed, the dormant period of the subjects is the best time. What has to be done is to lift a good-sized plant from the open ground and detach as many of its roots as may be deemed expedient and safe. The detached roots should then be taken to the potting-shed and cut into lengths of about 1½ inches, taking care at this juncture that the uppermost ends of the roots, *i.e.*, the end which was nearest to the rootstock before being cut away, are kept uppermost throughout. By laying the root lengths in order as cut, no subsequent confusion need exist on this head, and the work of cutting up completed, the root-cuttings should be forthwith inserted. The manner of dealing with these cuttings subsequently is to prepare some well-drained pots or pans, the former for preference, and slightly more than half fill them with rather sandy soil. At this point it will be necessary to gauge the cuttings and to

determine whether more soil should be added to the pots or some removed. When the cuttings are inserted and the work completed, the apical portion of the cutting should be just visible above the surface of the soil and level with the rim of the pot, the cuttings being placed around the interior of the rim in a not quite upright position. In this way the operator can judge for himself as to the work being rightly done. The cuttings should be placed around at about a quarter of an inch apart or thereabouts, or at a greater distance if there is no scarcity of room. When the root-cuttings are in position, the remaining space should be filled with soil, taking care not to displace the cuttings in doing this. By making the soil of a sandy nature, new root-fibres are more quickly formed when, presently, top growth begins. The best position for these pots of root-cuttings is in the greenhouse frame, where a slight warmth, say, of 45° or 50°, obtains. Given one good watering when the work is completed, the pots in the position and warmth suggested will require no more for a fortnight. If no frame is at command, the pots of cuttings may be plunged in fibre or sand in pots of much larger size, and, by placing a sheet of glass over all, secure that degree of uniformity which is so desirable.

All that is now necessary is a little patience, and a month or six weeks may elapse before any signs of new life are seen from the apices of the cuttings. First we see a swelling or callusing of the surface, and subsequently miniature protuberances that develop into shoots, the latter often appearing quite numerous. So much so is this the case that in the larger-rooted species of plants, such as *Anchusa italica* and the Japanese *Anemones*, it has been found desirable to halve or even quarter the roots longitudinally before inserting them. The most serviceable size of root is that about the equal of a cedar-wood pencil for the largest, and say half that size for the smallest. This way the largest roots are secured to the plant. Though I have recommended covering the cuttings with a glass frame, care should be taken to ventilate now and again and to avoid that wet, stagnant condition which may give rise to decay rather than growth. Forcing by an excess of heat is injurious, and will merely produce the top shoots before any root-fibres are present to sustain life. Fleshy roots full of vitality are essential; old roots that have become hard and wiry are usually valueless. The after-treatment of these root-cuttings, and when they shall have become little plants, is simply that given to small seedlings requiring to be individualised to produce the best results; and when this is done the genial conditions of a frame or a greenhouse will be found highly beneficial. There need be no hurry to do this, however, and only when small leaves appear, giving evidence of activity at the root, should the work be taken in hand. A host of plants respond to this particular treatment, but I have no intention of preparing an exhaustive list. A few of the most important, however, are *Anemone japonica*, *Anchusa*, *Gaillardia*, *Senecio pulcher*, *Primula* (the roots of which are small), *Stokesia*, *Eryngium*, *Echinops*, *Statice* and the perennial *Poppy*, none of which, save the *Anemone*, affords the least external evidence of an amenability to respond to a method of treatment which is as valuable to the gardener as it is interesting and instructive to the student.

E. H. J.

NOTES ON CARNATIONS.

Propagating Perpetuals.—There exists such a pronounced diversity of opinion regarding the time most suitable for propagating Perpetuals that a brief pronouncement on the benefit of autumn propagation may be permitted before proceeding to details. Those who, quite reasonably, defer propagation till after the New Year opine that nothing is gained by rooting the plants earlier, and that as much progress is made by plants prepared on their system as by those rooted in the autumn. Very much must depend in either case on the condition of the plants that provide the cuttings, and on the treatment the young plants receive. It is obvious that, in the less southerly parts of the country, plants which have been in a glass structure for three to four months cannot produce equally satisfactory cuttings to plants which are only newly put under house treatment; and while it is true that autumn-struck plants make very slight progress up till January, they do possess a decided advantage in having a root economy far in advance of those struck in that month, and this gives the young plant when it is hard pinched a dynamic force which produces a strong early framework, or foundation, rather, that a late-rooted plant cannot in the nature of things ever overtake. These are the two chief points in which, in my opinion, autumn propagation has the advantage of propagation early in the year; that is to say, a better type of cuttings is available, and a healthier, more robust type of plant results. I think, too, that cuttings are rooted with more facility in the autumn than at the more advanced period.

The Best Cuttings.—There is nothing new that can be said regarding the shoots which produce the best cuttings, long experience showing how those produced well up the stems are the most prolific of bloom. Moderately strong shoots are to be preferred; but it is not important, as some think, to secure or retain a heel to the cutting, one cut across under a joint, or, indeed, above a joint, rooting quite as well, and usually making a shorter type of plant.

For the last year or two I have had the cuttings put three in a 2½-inch pot in the usual sand, the reason for this being that the rooted material is more easy to handle. The pots are plunged in a propagating-bed, the material kept wet and the temperature 55° to 65°, roots being emitted in time to permit removal from the propagating-bed in twelve days onwards. It will be seen that the cuttings are for so brief a period subjected to what many would conclude to be a dangerous heat that no harm can possibly come to the plants.

Cuttings Flagging.—Not a few beginners fail at this early stage through allowing the cuttings to flag. This is fatal. If the moisture is not sufficient to provide against flagging, then glass should be placed over them till roots are emitted. No delay must occur after rooting and a few days' subsequent hardening on a bench or stage in potting the young stuff singly into 2½-inch pots, using a sandy, open compost and merely knocking the pots gently to settle the soil about the roots. In a warm structure root action will begin at once, and in a short time the plants should be transferred to a cool structure, growth at this time of the year being of no importance. Once the soil in the 2½-inch pots is ramified by roots, shift on without delay, and by no means indulge in stopping. If stopped, only one or two

breaks will be made, and these weak ones. Leave this cultural expedient till January at the very earliest, when breaks will be produced abundantly and strong shoots follow. R. P. BROTHERSTON.

THE AUTUMN TREATMENT OF LAND.

(Continued from page 512.)

For Sowing or Planting in February and March.

Much land may not be ready for cultivation till the spring; the following crops are suitable for land that has been lying vacant during the winter. Work may begin in February or as soon as genial weather sets in:

1. Potatoes .. Early varieties.
2. Beans .. Broad and Kidney.
3. Peas .. Early and mid-season.
4. Cauliflowers Early.
5. Round Spinach.
6. Spinach Beet.

1. Potatoes.—The land should be thoroughly dug and forked during the winter and worked into a friable condition. The common distance to plant for first-early varieties is 4 inches in depth, 12 inches between the sets and about 20 inches between the rows. For midseason and late varieties the sets may be 15 inches apart and 24 inches to 30 inches between the rows. For further information see Leaflet 173 on Potato Growing.

2. Broad Beans.—Plant $3\frac{1}{2}$ inches to 4 inches deep, with 18 inches to 24 inches between the drills and 4 inches between the seeds.

Kidney Beans.—Plant 2 inches deep, 2 inches to 4 inches apart in the drill, and 18 inches to 27 inches apart in the rows. One pound of seed will plant 150 feet to 200 feet of drill.

3. Peas.—Sow in a flat drill from 2 inches to 3 inches in depth according to soil—in stiff soil shallow, and in light soil deep. Dwarf varieties should be sown in rows 18 inches to 2 feet apart; tall varieties further apart according to height. Early Peas require 1lb. to 70 feet of drill; late varieties 1lb. to 85 feet of drill.

4. Cauliflowers.—The distances are the same as for Cabbage.

5. Round Spinach.—Sow 1oz. of seed to 65 feet of drill, about 1 inch deep, in rows 12 inches to 15 inches apart.

6. Spinach Beet.—Sow as for Round Spinach, but thin out to 8 inches or 10 inches apart in the rows.

Information as to the application of fertilisers to these crops will be found in Leaflet 106.

CLASS B.—GOOD GRASS LAND BROKEN UP FOR SPADE CULTIVATION.

A great extension of allotments and other holdings under spade cultivation may also take place. Many acres of grass land might be utilised in this manner, especially in the neighbourhood of large towns. Such land must be treated in a different way to the cultivated land described under the previous heading.

In the first place the land should be bastard trenched. To begin with, the turf should be skimmed off in a thin layer 2 inches to 3 inches in depth from a trench, which should be 18 inches to 2 feet broad. The first spit of soil immediately below the turf should be removed. The bottom soil should then be stirred to a depth of 6 inches with a pick, digging fork or spade according to the nature of the subsoil. The turf layer from the next trench should then be laid upside down on the stirred bottom of the first trench, and the first spit of soil placed above it. This process should be continued till all the land has been dug over, the turf and first spit of soil from the first trench being used to level up the last. Land of this character is often very fertile, and should give a good yield

THE CATMINT (NEPETA MUSSINII) GROWING IN A DRY WALL.

of Potatoes or other planted crop the following summer. It can, however, seldom be used for crops raised from small seeds in the same year as it is broken up, for two reasons—(1) unless the turf is very good and free from weeds, the result of the cultivation may bring up and favour the growth of a number of weeds which have hitherto been kept under. A good deal of hoeing may be necessary to keep these down, and this may interfere with the seedlings. (2) Old grass land is often infested with wireworms (the young of the click beetle) and leather-jackets (the young of the daddy-long-legs). These insects may completely destroy the crop as soon as it begins to grow. Treatment for these pests is given in Leaflets 10 and 11, but as the methods advised may not be available at the present

time, the land should be frequently hoed and the weeds kept down so as to deprive the insects of their food for some months. Lime may also be worked into the land.

CLASS C.—DERELICT LAND.

In many districts fertile grass land will not be available for cultivation by spade labour, and if additional land is to be brought under tillage, poor soil or waste land must be broken up. There are many acres of land of this class available, especially in the neighbourhood of large towns, but care is needed in treating it if it is ever to bear a satisfactory crop. The following treatment is recommended: In the first place, all rank growth of weeds should be cut down with a scythe. If the weeds are of a soft nature, they might be put in heaps with any available grass for making into a compost, or if annuals and free from ripe seeds, they may be dug in at once. If of a fibrous or woody nature, they should be burnt. The land might then be skimmed and bastard trenched as before advised, but the greatest care must be taken (1) not to bring the subsoil to the top, and (2) to clear out the roots of such weeds as Docks, Couch Grass, Creeping Buttercup, Convolvulus, Nettles, &c. Time spent in the careful eradication of such weeds will be well repaid.

Land of this character, when freed from weeds and properly trenched, will bear a useful crop the following year if properly manured. As stable or farmyard manure will probably not be available in such places, it will be necessary to supply the plant food from other sources. The chief ingredients required to secure satisfactory growth are (1) nitrogen, (2) potash, (3) phosphates. Nitrogen can be supplied by digging in all soft vegetable matter such as grass, leaves of trees, and decaying vegetable matter of any sort. The manure of any kind of animal may be used. Poultry and pig manure should be well mixed with earth on removal from the pens or sties before applying it to the land. Potash may be supplied by collecting and burning all kinds of woody material, such as hedge clippings, prunings from trees, &c. The ash should be carefully saved in bags and kept dry. It is especially useful on land that is to be cropped with Potatoes.

Seaweed is a valuable potash manure, and should be collected at all rocky sea coasts (see Leaflet No. 254). Phosphates will not be easy to supply from natural sources, unless large quantities of fish waste are available, but phosphatic fertilisers such as basic slag, superphosphate and bone-meal should be easily procurable through the usual trade sources. Lime will be required in many cases, and should always be applied to rich pastures after breaking up. It should be worked into the surface layer when the land is dug. The advice as to insect pests and weeds under Class B applies with even greater force to this class of land, and great care should be taken to get rid of both before the land is sown or planted with any crop.—*Board of Agriculture's Special Leaflet No. 1.*

DRY WALLS IN SUMMER AND WINTER.

IN common with most other features of the outdoor garden, the dry wall is more beautiful and interesting during the summer months than in winter; yet where proper thought is given to winter effect, quite good results can be obtained even during the shortest days. There are a number of plants which are beautiful at both seasons, one of the best known, perhaps, being *Cerastium tomentosum*. In the accompanying illustration, which represents dry walls during the early summer, a large cluster of this is shown just to the right of the bold stone

that come to mind as being suitable for adding splashes of colour and some considerable interest to the dry wall during the winter season. In the other illustration we see a particularly useful plant for winter effect, viz., the Catmint (*Nepeta Mussinii*). This is beautiful in summer when laden with its lavender blue flowers, while in winter its glaucous-hued foliage harmonises well with that of our garden Pinks. G. B.

FINGER AND TOE DISEASE IN GREEN CROPS.

THE past summer has been particularly favourable for the spread of the disease of Cabbages, Cauli-

At this time of the year the swollen roots of in the ground and the fungus granulates and forms myriads of spores, which escape into the soil ready to attack future crops. It is important that measures should be taken at once to remove all plants that are badly attacked, also all stalks of Cabbage, Cauliflowers and other greens from which the heads have been gathered. The diseased roots should be burned at once, and not thrown into heaps to decay, as is too often the case.

Another method of checking the spread of the disease is during the autumn to dress the land on which Brassicas are to be grown next year with quicklime at the rate of about half a bushel to 30 square yards. Earth-slaked lime is the best form to apply, although ground white lime

A DRY WALL AND STONE STEPS IN SUMMER. MANY OF THE PLANTS WOULD ALSO BE BEAUTIFUL IN WINTER.

steps, its small white blossoms being borne in such profusion as to give rise to the popular name of "Snow in Summer." In winter this plant would be a mass of silvery grey foliage that would contrast well with darker-hued plants that surround it. Pinks of many kinds, especially the old common Double White, may also be employed for the same purpose. Then there is the grey-leaved Cotton Lavender, the foliage of which is beautiful at all seasons. *Saxifraga apiculata*, which often opens its pale yellow flowers in January; dwarf Lavender bushes; *Cotoneaster microphylla*, with scarlet berries, to be planted in the soil at the base of the wall; Wallflowers of the Early Paris type; Edelweiss, with grey foliage; and the Cobweb Houseleek, which likes a dry position sheltered from heavy rains, are a few others

flowers and other Brassicas. The exceptionally dry weather has had the effect of checking the growth of the plants, and they have been unable to resist the attack. The diseased condition of the plants is so well known that a description is unnecessary. The disease is caused by a fungus (*Plasmodium brassicæ*) which exists in the soil during the winter (and, indeed, if no suitable host is present, for several years) in the form of minute spores. These spores are taken up by the roots of plants belonging to the Cabbage family, and once inside the roots they form a plasmodium or jelly-like substance, which feeds upon the contents of the cells. The presence of this foreign substance sets up an irritation which causes excessive growth to take place in the roots, eventually forming the swellings known as club, or finger and toe.

is very good. It is important that the lime should be dug into the ground as quickly as possible, as exposure to the air causes deterioration. Gas lime is helpful in checking the fungus, but it should be exposed to the air for several months before digging it into the soil, in order to get rid of the poisonous compounds which are always present in fresh gas-lime.

Earth-slaked lime is obtained by placing the lump lime in heaps over the bed to be treated, completely covering each heap for a few days with earth. Under these conditions the slaking takes place gradually and in the partial absence of air. For use it is only necessary to remove the earth covering and dig the powdered lime into the soil, scattering a little in each trench as the work proceeds. A. E. B.

THE LITTLE GARDEN.
FURTHER PRIZE DESIGNS IN OUR COMPETITION.

IN last week's issue all the first prize designs and some others were shown, and we now reproduce a further series. The five plans for Site No. 1, given at the foot of this page, show very well what a large variety of treatment is possible even within such narrow limits as are afforded by a little suburban garden.

The second prize for Site No. 1 was awarded to Mr. Burnett Orphoot. The feature of it is the skill with which a long grass alley has been secured on the south side of the house. This would yield a very pretty little vista from the seat under the trees in the main garden. The seat at the end of the grass alley would only be satisfactory when the roadside hedge had grown up. Otherwise the front garden is too much cut up and the borders are too narrow. The bed of Tree Pæonies is rather a disturbing element on the main lawn, and the planting scheme for the circular beds is not very well conceived. The hedge treatment at the back, cutting off the little space for frames and small crops, is well managed, and the herbaceous borders are adequate in width.

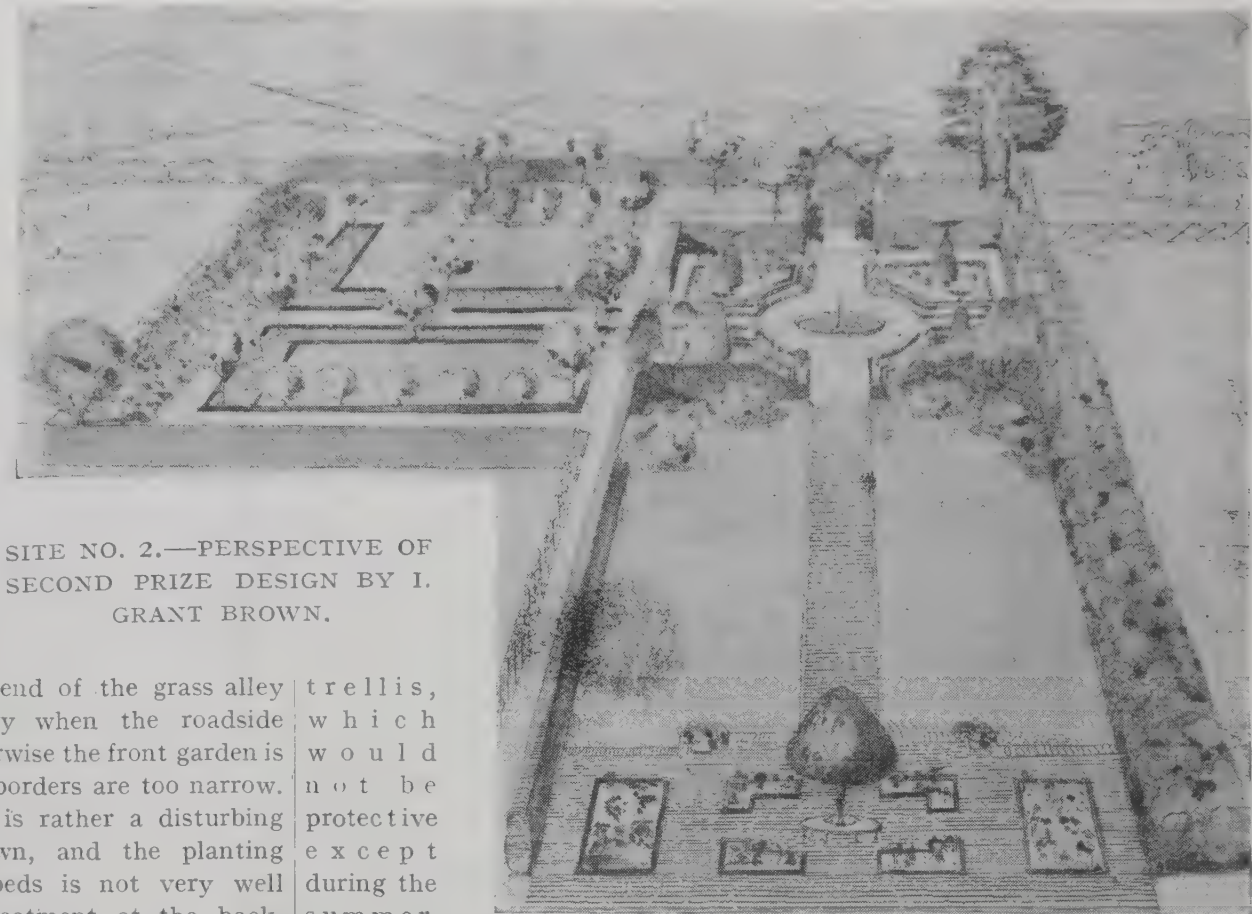

The third prize for Site No. 1, like the second prize for Site No. 3, went to one of our American readers, Miss Elizabeth Leonard of Cambridge, Massachusetts. Her practical outlook on the problem is shown by her provision of a drying-yard. This is somewhat imperfectly screened from the garden by a Sweet Pea

It would have been better if this drying-yard had been disposed at the end of the site. The stepping-stones provided in the grass on the south side of the house are not found in gardens of good English practice, but would be practical on soft ground. The tool-house and frames are neatly placed, and the vegetable garden divided well from the flower garden by a Privet hedge. The front garden is shapely; but Miss Leonard's weak spot in this, as in other of her designs, is the extreme narrowness of her paths. Taken as a whole, however, the design is thoroughly satisfactory, because it does not attempt too much, a common fault on very small sites, and it could be well managed by a householder of small means.

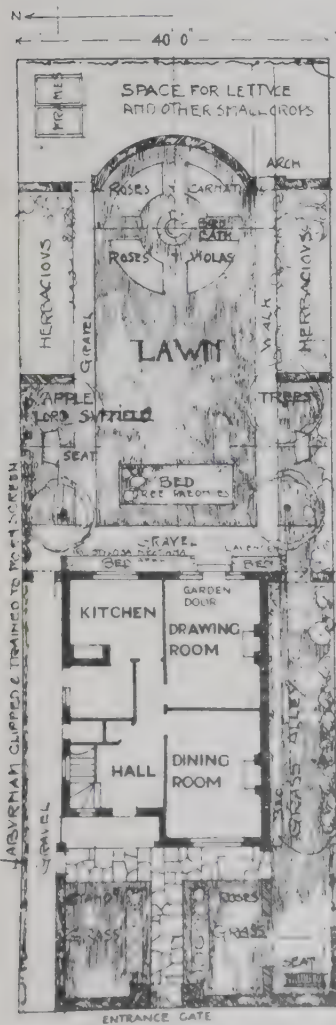

Of the designs for Site No. 1 to which book prizes were awarded, we now illustrate three.

Mr. Archie Paton has erred in the direction of cutting up too much the space at his disposal. Within such narrow limits such a feature as a sunk garden should not

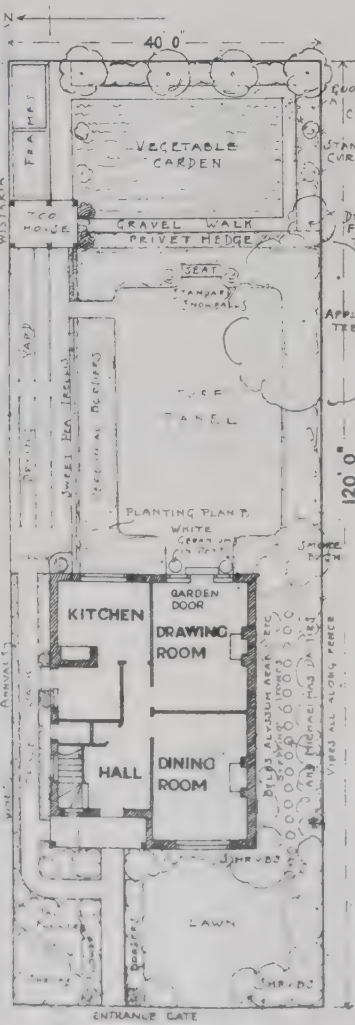

trellis, which would not be protective except during the summer, and the spectacle of the linen would not be very agreeable to the neighbours on the north side. have been attempted, especially as it necessitates a little system of drainage to prevent

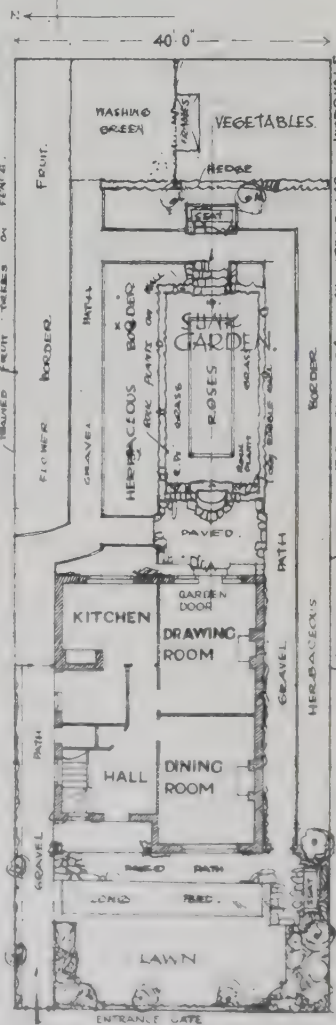

SITE NO. 2.—PERSPECTIVE OF SECOND PRIZE DESIGN BY I. GRANT BROWN.

Second Prize.—B. N. K. Orphoot.

Third Prize.—Elizabeth Leonard.

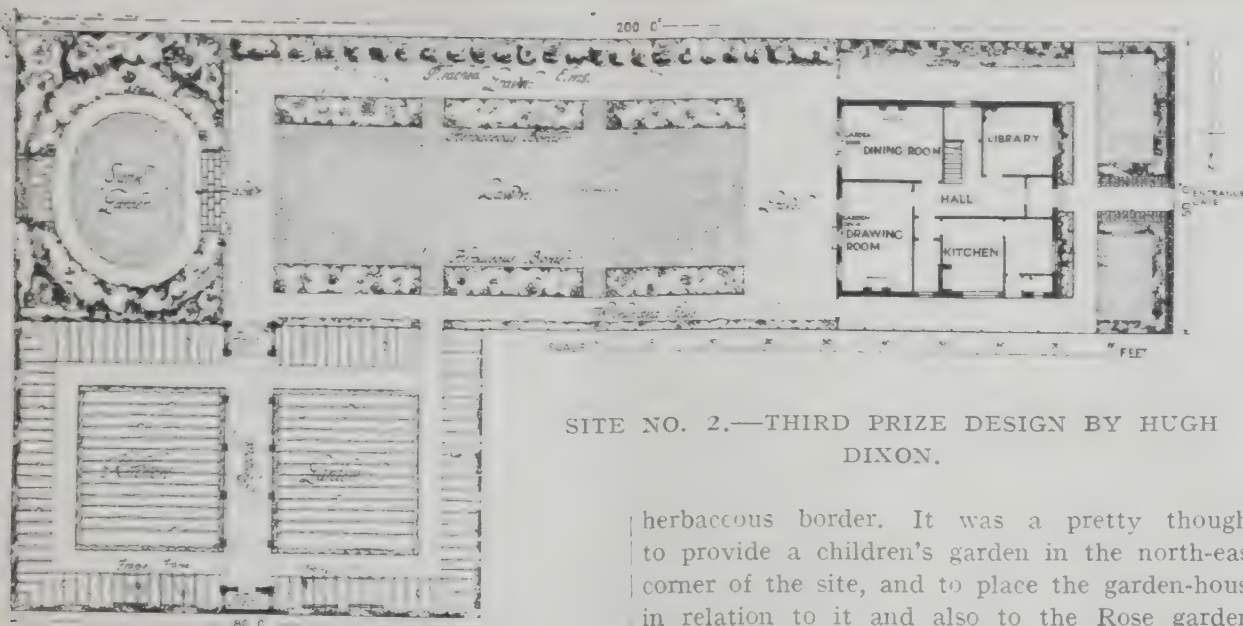

Book Prize.—Archie Paton.

Book Prize.—B. M. Cory.

Book Prize.—Isobel Harding.

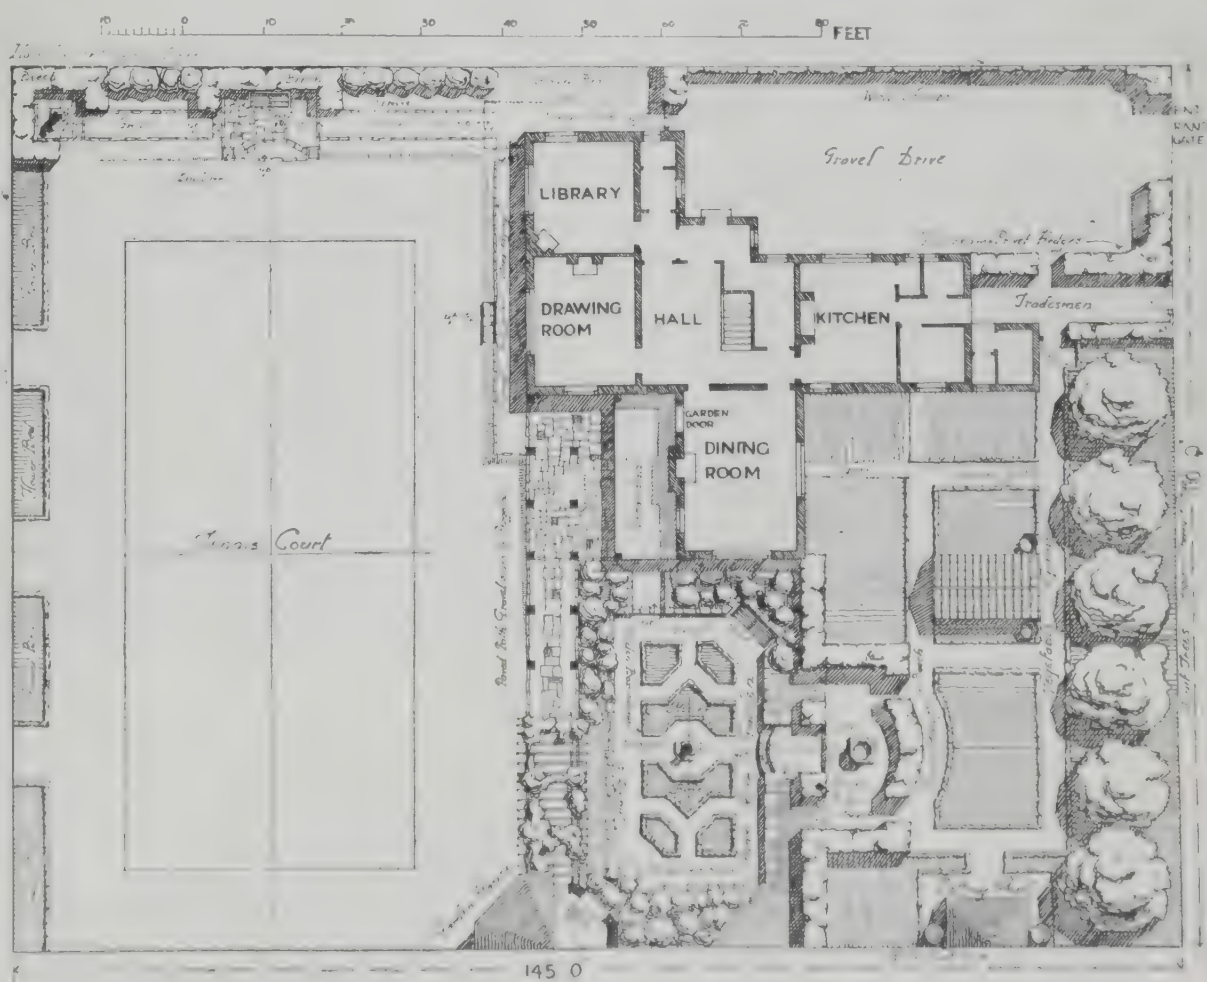

SITE NO. 2.—THIRD PRIZE DESIGN BY HUGH DIXON.

herbaceous border. It was a pretty thought to provide a children's garden in the north-east corner of the site, and to place the garden-house in relation to it and also to the Rose garden. Practical considerations have not been forgotten, for the frames are disposed in a space enclosed by a hedge. Miss Grant Brown's planting plans were thoroughly well considered, but the provision of a standard Holly on the brick-paved space outside the main sitting-room is a doubtful feature.

In the case of Site No. 2 the third prize was won by Mr. Hugh Dixon. The design is simple and straightforward, and its chief defect is that the treatment of the lawn bears no very direct relation to the house. In a garden of this size, moreover, it is very desirable that the

to the position of the pergola. This feature has achieved an immense popularity in English gardens, but its purpose and character are not always well conceived. It should ideally be used as a connecting link between two or more definite points in house or garden. It is appropriate, for example, to build a pergola leading from a house verandah to a summer-house. In the case of this plan, however, the pergola occupies a detached position, dividing the two parts of the kitchen garden and connecting an isolated arch with a not very attractive shed. Nevertheless, the competitor has deserved his prize by reason of the simple and unlaboured way in which he has utilised the site.

For Site No. 3 the third prize was won by Mr. Kenneth Dalgliesh. This design is dominated by the tennis court, which is correctly placed north and south. The flower-beds to the west of it are a somewhat doubtful feature. They would look rather patchy, and a continuous border would be more restful. The north end of the lawn is prettily provided with a seat and a statue of Pan, backed by buttressed Yew hedges connected by groups of Planes or Californian Limes, and attractively shown by a perspective to be reproduced next week. This feature would look well as seen from the library and drawing-room windows. The verandah is connected with a little garden-house by a long pergola, which divides the lawn from the flower parterre to the east. Backing the

SITE NO. 3.—THIRD PRIZE DESIGN BY KENNETH DALGLIESH.

area to be treated should be subdivided somewhat by walls, trellises or hedges, so that the eye may not take in the whole scheme at one sweep. There is no more valuable quality in garden designing than a touch of surprise. The visitor should be led from one point to another with a sense of expectancy, but that feeling would not be aroused in the garden which Mr. Dixon has designed. Criticism may also be directed

sunk Rose parterre and dividing it from the vegetable garden is another arrangement of hedges, either Privet or Beech, neatly composed with a well-head. The vegetable garden is well screened from the road by a rank of standard fruit trees, and due provision has been made for frames and potting sheds.

Further designs will be illustrated next week.

L. W.

it becoming a morass. A good point, however, is the arrangement of the garden on the axial line of the drawing-room garden door, with the vista terminating in a seat backed by a hedge. Behind this hedge is a little plot for vegetables and frames and a washing-green. The latter provision is typical of Scotland, where it is almost always made. Mr. Paton has arranged his entrance differently from most competitors, in that he puts the gate at the north-west corner of the site, and thus avoids cutting up the little garden in front.

Miss B. M. Cory's scheme is extremely simple, and she makes no attempt at providing any vegetable space. The treatment of the main garden is shapely enough with its broad borders flanking a grass plot studded with standard Roses. This leads to a little space with a sundial flanked by segmental Rose-beds. The main defect of the scheme is that too much bedding space is provided. There are borders on each side of the grass strips at the front and south side of the house, as well as those of varying width which are all round the main garden.

Another scheme much on the same lines, but more carefully worked out, is that by Miss Isobel Harding. She makes a main feature of eight shower Roses in circular beds, each approached separately from the main path which leads up the middle of the site. The shapely Yew hedge is a pleasant feature, and provides a suitable screen for a frame on one side and a few trees on the other. The curved outline of the raised borders makes a change, but the scale of the garden is really too small for little refinements of this kind. Good use is made of the south wall of the house for the growth of Plums. The entrance is well managed, and, assuming a good growth for the hedges, the space to the right of the gate would make a pleasant little garden.

The second prize for Site No. 2 went to Miss I. Grant Brown, and we show her design by the perspective which accompanied the plan. It represents the view which would be seen from the chief rooms of the house. The scheme shows skill and thought. Good garden pictures are seen from the dining-room and drawing-room across the brick-paved terrace and eastwards to the hedge which screens the lawn from the Rose garden. The kitchen garden is well screened by a Yew hedge running east and west, and is provided with a broad

ROSE-GROWING IN TOWN GARDENS.

Roses from Cuttings.—Of the several ways of propagating Roses, striking cuttings is by far the easiest, and therefore commends itself particularly to the town gardener whose time is limited. It is true that only the most vigorous varieties are likely to succeed and give satisfaction when increased in this way, but as these should form the major part of the townsman's stock, the method is often useful to him. It is an exceedingly simple process, which has frequently been described, and the directions need only be gone over here in order to emphasise those points which ensure success.

A Cutting is prepared from seasoned wood of the current year which has been removed

Best Varieties for Cuttings.—Those that are especially suitable for raising in the manner described are the *Wichuraiana*, *Multiflora* and other climbers, as well as Hybrid Teas or Hybrid Perpetual Roses of rampant growth, such as *Hugh Dickson*, *Frau Karl Druschki*, *J. B. Clark*, *Ulrich Brunner* and *Mme. Abel Chatenay*.

Layering.—Another useful method of raising own-root Roses is to peg down and layer branches just in the same way as one does with Carnations, forming a "tongue" where the stem is bent upwards by half severing the shoot in an oblique direction just below an eye. This tongue must be pressed well down into some sandy soil, and the shoot must be carefully tied into position so that it does not move. When rooting has commenced, it may be severed from the parent stem. Here, again, it is important to note that

HINTS ON PLANTING ROSES.

MOST amateurs are apt to afford Roses too rich a soil when planting, and as the season is close upon us once more, I would like to give a few practical hints, resulting from careful observations and experience among these popular flowers. There is one piece of advice in the cultural directions of almost all catalogues that needs a little qualification or explaining. They advise deeply dug and well-manured soils, and end by saying: "In fact, it is difficult to give the Rose too rich a soil." When growing strongly and able to assimilate such food, I agree with them; but not until the roots are well established would I dress the soil so heavily as it is often treated. Digging the ground deeply and applying a good lot of manure to the bottom soil, which we can never reach again, are correct enough; but it is more beneficial, as well as economical, to apply surface-dressings, and lightly fork these in when the roots are in a condition to assimilate the nutriment at once. I have known the soil so strong that the new roots could not even get a satisfactory start, and the whole had to lose much of its strength before they could forge ahead, simply because it was too strong in the first place.

There is another point not sufficiently borne in mind; that is, to supply manures more suitable to the soil. What will suit a light, sandy compost is by no means so good for a stiff and heavy soil. The latter needs soot, wood-ashes and a little bone-meal; also lighter animal manures, such as that from the stable. On the contrary, we should make use of night soil, pig and cow manure upon a light and porous soil.

The necessary drainage must be attended to upon

wet and cold soils, or all other labour and expense is more or less wasted. The time of planting is also of importance, and this a little in accordance with the nature of your soil. If naturally wet and cold, I would prefer early spring, choosing autumn or very early winter in the case of drier ground. Should the plants carry much wood, I would shorten this back at the time of planting; not exactly prune them, but lessen the strain upon the roots by cutting away about half of the wood. It is not wanted, for it is much safer to closely prune all Roses the first season of planting, and we may as well reduce long shoots now.

Do not choose highly fed plants with coarse and sappy growth; rather aim for medium-sized plants carrying riper and better-matured wood. Cut off any coarse or bruised roots, plant firmly, and be sure the junction of stock and Rose is a couple of inches below the surface.

A. P.

A GARDEN OF ROSES. NOW IS THE TIME TO PLANT FOR NEXT YEAR'S EFFECTS.

with a heel and is then trimmed by having the lower leaves removed. The top should be cut off, leaving the shoot from 9 inches to 12 inches long when ready for planting. A drill is made by cutting down about six inches with the spade and pulling it over slightly so that a V-shaped opening is made, in the bottom of which about half an inch of sand should be placed. The cuttings must be planted so that the base (or heel) of each rests firmly on the sand. During the winter months they should be looked over occasionally, and any that have been loosened by the action of frost must be pressed down and made firm again. By the following spring the base of each cutting will have callused over, and if the earth is then kept slightly moist, roots should be emitted during the summer. The best position for the bed is under a wall facing north, for it is important that the cuttings should be shaded when they are commencing to root.

the soil must be kept moist during the ensuing summer.

Division.—There is yet another method of increasing one's Roses which I have found particularly useful in dealing with Dwarf Polyanthas. These are for the most part of very free growth, producing basal shoots in great profusion, and if used for an edging to beds of other Roses it is not desirable that they should occupy too much space. In November those that have become bushy should be carefully lifted, and they will generally be found to have emitted roots from the bases of several large growths, which will allow of each being separated into two or three good-sized plants. If this is done with the secateurs, care being taken not to injure the roots, the growth of each piece should be fully equal to that of the parent plant.

P. L. GODDARD.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Cucumber Plants from which winter supplies are expected should now have reached the top of the trellis, and may be allowed to carry a few fruits, but nothing beyond what is necessary for the daily supply should be allowed to remain on the plants during the winter. Let the young Cucumbers be pinched off while quite small, so that they do not tax the energy of the plants. Constant attention to stopping and tying will be necessary, so that the foliage may not become crowded. Remove rough, overgrown leaves as it becomes necessary to make room for young fruiting shoots, which may be stopped at the first or second leaf beyond the fruit, according to the space available.

Peach Trees.—The pruning, washing and tying of permanent trees in the early Peach-house should be accomplished as soon as possible. Remove as much of the old wood as can be spared before the trees are untied, also shoots which have become too gross to bear fruit. The trees may then be carefully washed with soft soap and water, and if mealy bug is present in the house, the trellis and walls must be washed with some insecticide of sufficient strength to destroy it. While this is being done, care must be taken to keep it from coming in contact with the trees or the border.

Plants Under Glass.

Pelargoniums.—Young plants of show and decorative Pelargoniums which were rooted during the summer should now be ready for potting into 5-inch pots. The compost may consist of two-thirds sandy loam, and the remainder of leaf-soil and dried cow-manure, with sufficient sharp sand to keep the soil open. Pot moderately firmly in well-crooked pots, and place the plants in a pit where sufficient fire-heat can be applied to exclude frost. When the roots have penetrated the new soil, ventilation must be freely given to keep the plants hard and stocky. Old plants which were recently potted will also require free ventilation with the same object in view.

Carnations.—The Tree Carnations will now be flowering freely, and should receive careful attention with regard to tying and watering. Prick up the surface of the soil and apply frequent light dressings of artificial manure previous to watering with clear soft water. Ventilate the house freely in order to produce good, healthy growth. Sufficient fire-heat ought to be applied to keep the night temperature at 50°.

Chrysanthemums.—Many of the large-flowering varieties are opening, and will require a good deal of attention to obtain the best results. Keep the atmosphere of the house moderately dry and ventilate freely when the weather permits. If foggy weather sets in, a little fire-heat may be applied to keep the air dry. All late-flowering varieties should be given a liberal supply of stimulants to plump up the buds. Ventilate the house freely and only apply fire-heat to exclude frost.

The Flower Garden.

Dahlia Tubers, Gladioli, Salvia patens and tuberous Begonias should all be lifted from the flower garden and placed in some dry, frost-proof shed for the winter. The Salvia roots are best placed in boxes of dry sand. Cut the stems to within 6 inches of the ground before the plants are lifted.

Roses.—If new plantations of Roses are contemplated, there is no better time than the month of November to accomplish the work. The ground for the purpose should be trenched as soon as possible, and a good dressing of farmyard manure applied. The beds may then be left to settle before planting takes place.

Sweet Peas in Pots.—The present is a good time to sow Sweet Peas in pots for planting in the open garden during the spring. Three or four seeds will be sufficient for each pot, and when the plants are through the surface they should be placed quite close to the glass in a cool pit and freely ventilated during suitable weather. In favourable districts the seeds may be sown

in the open, but a warm south border should be chosen for them, and great care will be necessary to protect them from slugs and mice.

The Rock Garden.—Any alterations which are contemplated in the rock garden should be accomplished as soon as possible, and any plants which have been propagated during the summer and are considered quite hardy may be placed in position at once, leaving the most tender subjects under a hand-light or cold frame until the spring. If dry weather continues, many of the plants in exposed positions will require water. Fallen leaves and decaying matter of all kinds should be removed, or some of the most tender plants may be lost in consequence. Keep the surroundings quite free from weeds by the frequent use of a small hoe.

The Kitchen Garden.

Asparagus-Beds.—As soon as the growths are sufficiently ripe, they should be cut to within a few inches of the ground and burned. The surface of the beds may then be lightly pricked over in readiness for a dressing of farmyard manure, which should be allowed to remain on for the winter.

Cabbage.—A second plantation of Cabbage should be made now to provide supplies for use in April and May. If sharp weather prevails during the winter, this may prove a more serviceable crop than the earliest plantation.

Winter Salad.—To ensure a full supply of salad during the winter, all empty frames must be filled at once with plants of Lettuce and Endive, which should be carefully lifted from the open garden. A thorough soaking of water ought to be given several hours before the plants are lifted, and again after they are placed in the frames. If box frames are available, they may be placed over salad plants growing in the open. Chicory may also be lifted and placed in some dark chamber with sufficient heat to start the roots into growth. If only a small supply is necessary, the roots may be potted and covered with an inverted pot of the same size, which may also be covered with leaves in order to ensure complete darkness. Mustard and Cress should be sown weekly in quantities according to demand.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Runner Beans.—Now that the supply of Beans as a green vegetable will be finished, so far at least as outside plants are concerned, the plants should be gone over, gathering all pods that have been allowed to mature. Where economy has to be practised, a number of the best of these should be saved for seed purposes. These must be stored where they will dry slowly. The seeds should be taken from the other pods and cooked; they make a most delicious dish.

Horseradish.—As the weather becomes colder the demand for Horseradish increases, and instead of digging a root here and there, as is usually done, it would be better to dig up a few rows, if not the entire plantation, and store the roots in sand where they can easily be got at when wanted. It will be advisable to grade the roots, selecting the largest for the season's demand; while the secondary roots should be stored separately for spring planting, much after the style of treating Seakale.

Asparagus.—It may seem early in the season to think about the forcing of this excellent vegetable, but as the craze of the day is for variety and things out of season, it is none too early to consider the forcing of Asparagus. Treated on proper lines it is doubtful if we realise how accommodating this vegetable is for forcing purposes. Assuming that the crowns are thoroughly matured, a few may be lifted at any time after this date and placed in boxes in any heated structure and heavily shaded. It is surprising how soon a sufficient quantity for a nice dish can be cut. It should be remembered that Asparagus roots suffer very much if exposed to the air for any length of time, so that the sooner they are planted after being lifted the better.

The Flower Garden.

Planting Roses.—Although these may be planted more or less successfully from now till the beginning of March, there is no doubt that the earlier they are planted the better the results.

Herbaceous Plants.—Most of these will now have passed out of flower, and a careful note should be made of those that need to be replanted. Unless the border has been regularly top-dressed, these plants soon become exhausted, and consequently the growths become weak and the flowers small. Where it is not possible to replant the entire border, much can be done by reducing the stronger-growing plants that are encroaching on the others and cutting away all dead stems. As has frequently been pointed out, the choicer subjects had better not be disturbed till the spring. All plants should, if possible, be correctly named, and as wooden labels rarely last more than two seasons, these ought to be renewed as occasion requires.

Plants Under Glass.

Schizanthuses.—Those plants that are intended to make large specimens should now be put into their flowering pots, and as these plants are rather free-growing, the compost should contain some good loam, with the addition of some artificial manure. After potting, the plants ought to be placed in a cool house not far from the glass, and for a time little or no water will be required.

Primulas.—The majority of these, whether of the obconica or sinensis type, should now be placed in a house where the temperature can be maintained at about 50°. The earliest of these will now be well established in their flowering pots, and may be given some weak liquid manure. Plants intended for flowering later should be potted on and placed near the glass. As Primulas suffer from damping, the atmosphere must be kept fairly dry.

Humea elegans.—These are possibly the most fastidious plants in the greenhouse to bring safely through the winter. No matter how strong and healthy the plants may seem, the slightest neglect in watering will most assuredly tell against them. Therefore it will be necessary to keep a watchful eye on them during the next three months, and, as has already been pointed out, use the water-pot with caution.

The Hardy Fruit Garden.

Morello Cherries.—The pruning and cleansing of these trees ought to be proceeded with at once, in order that a great part of this work may be completed before very severe weather sets in. Where the trees have been infested with spider or other vermin, they should be entirely taken down and treated in the same way as Peaches. In pruning, all shoots that have borne fruit ought to be cut away, thinning out the others to not less than 4 inches apart. Unhealthy trees should have a little of the soil removed round the stem, replacing this with some good loam and burnt clay.

Loganberries.—The last of the fruit will now have been gathered, and unless the young growths were thinned out during the growing season, the result will be a perfect tangle. These should be thinned out at once to give the remaining shoots a chance of ripening before severe weather sets in.

Fruit Under Glass.

Peaches.—A start should now be made with the pruning and training of the earliest varieties. If the trees were disbudded properly during the summer, very little pruning ought to be necessary now. Assuming that the house and trees have been washed, as I have frequently pointed out, the trees should be tied up. In doing so, endeavour as far as possible to have them well balanced, and for this purpose do not hesitate to cut away all strong-growing growths that would be likely to run away from the others.

Strawberries.—Plants intended for forcing will by this time have filled the pots with roots, so that careful watering will be necessary, especially on fine days. If these are allowed to become dry once or twice, it almost spells ruin. On the appearance of hard frost the pots should be plunged up to the rims in ashes, when the plants can be taken in to force as required.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

BULBS FOR PRESENT PLANTING.

DURING the past few weeks nearly every post has brought us catalogues of "Bulbs for Autumn Planting," lists that remind us only too vividly that summer has flown and that the dreary days of winter will soon be upon us. Unfortunately for our gardens, and incidentally for the bulb merchants, these catalogues are, in the enjoyment of our summer flowers, too often put aside till a later date, or it may be they are entirely forgotten until a clearing-out of sundry useless material in the spring brings them to light, when it is, alas! too late to plant the many bulbous flowers without which our spring gardens would lose a great deal of their charm. The distribution of bulb catalogues during September is not, as many would suppose, due to any ulterior motives on the part of the bulb merchant; he is not trying to steal a march on his competitors, but he knows only too well that if we would get the very best from the goods he offers, they ought to be planted as early as possible after this date. It does not, of course, necessarily follow that they will be entire failures if not planted until considerably later; but there is everything to be gained by consigning these dried-looking roots to Mother Earth as early as possible in the autumn.

Where such bulbs as Daffodils, Hyacinths and Tulips are used for bedding, it may be impossible to plant them yet; the beds are still, owing to the mild weather, resplendent in their summer array, but, frost or no frost, they must soon be cleared. In the meantime there is a large host of smaller and lesser-known bulbs that may very well be planted without disturbing other kinds of flowers, and it is to these that I would call particular attention. The majority are specially suited for planting towards the front of a shrubbery, in beds of deciduous shrubs, in rock garden nooks, or, indeed, in almost any position where flowers of lowly stature will be appreciated during the early days of the year.

Undoubtedly one of the most pleasing, and the earliest of all to flower, is the so-called Winter Aconite (*Eranthis hyemalis*). Before January is far advanced the Buttercup-like flowers, each with its frilled green ruff, are studing the greensward of our lawns or carpeting the shrub-beds, reminding us that winter at last is fleeting and that Nature is slowly but surely awakening. But this little flower must be planted early, and planted in colonies. It thrives well almost anywhere, and is particularly pleasing in grass. Close upon it come the Snowdrops, the glistening white flowers of which are loved by everyone. Like the Winter Aconite, they thrive almost anywhere, but for naturalising in grass the common one, *Galanthus nivalis*, should be chosen. For rock garden nooks or shrub-beds the larger-flowered *G. Elwesii* may be planted freely. There are a number of other and choicer kinds, but for all ordinary purposes these two Snowdrops will suffice. Almost at the same time the beautiful little early Squills commence to open their dainty blue flowers. First comes the Two-leaved Squill (*Scilla bifolia*), to be followed by its near relatives the Chionodoxas, the best known of which is the charming little Glory of the Snow (*C. Luciliæ*), and subsequently by the rich blue *Scilla sibirica*. We cannot well have too many of these early flowering Squills

and Chionodoxas in our gardens, and as the bulbs are cheap, they may well be planted with a lavish hand. In addition to those already named, mention must be made of *Chionodoxa sardensis*, the gem of the whole family and one that flowers very early. In common with the other species it seeds freely, and will multiply rapidly if left well alone.

Then what shall we say of the dwarf Wind-flowers such as *Anemone apennina* and *A. blanda*? Both have delightful blue flowers, and I never could make up my mind which I liked best. So often the failure to grow these successfully is attributed to various mundane causes, when it is the date of planting that is at fault. The curious little tubers become badly shrivelled if left out of the ground long, and their stamina is thereby considerably diminished. Plant them freely and early in well-drained but not over-dry soil, and subsequently leave them well alone. They will thrive in grass or under the shade of deciduous trees, while colonies of them in the rock garden produce an effect in April of which few other plants are capable. Then there is our wild *Anemone* (*A. nemorosa*), with its dainty white flowers, and also Robinson's variety of the same, with pale blue blossoms. Both ought to find a place in our gardens, especially in woodland glens, where they are perfectly in keeping with the surroundings.

The Crocus family gives us a wealth of flowers from late autumn right on until spring is well under way, and it is necessary to get the corms of all kinds planted as early as possible. A dainty little plant that I have grown for some years, but which I seldom find in other gardens, is the Lebanon Squill (*Puschkinia libanotica*), sometimes catalogued as *P. scilloides compacta*. The flowers are white, striped soft blue, and, though small, remind one of a piece of old, rare china. Then there are the Muscaris, or Grape, Starch or Feather Hyacinths, the gem of which is Heavenly Blue, though there are several others, notably azureum and conicum, that are well worth growing. A careful perusal of a bulb catalogue will reveal other comparatively little-known bulbous plants that ought to find a home in our gardens; but they must be planted at once and, in the majority of cases, lavishly. Isolated Snowdrops and Crocuses, for instance, lose their charm.

S. X.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

ST. BRIGID ANEMONES (H. C. E.).—In ordinary circumstances the better way would be, if the seedlings have only recently vegetated, to retain them in the boxes, give them cold frame protection for the winter, and plant them out in March next or when all fear of severe frosts has passed. On the other hand, if you have to deal with a light, well-drained soil and a sheltered situation, the young plants may be put out at once. Some of the

leaves may be cut by severe frost, though, if you plant the tubers in drills 2 inches deep, the latter would be safe enough. When sowing seeds of these *Anemones*, it is advisable to sow in drills in the open ground in light soil, and, in the event of very severe weather, to protect with litter for the first season. When the tubers are large enough, they may be planted at a sufficient depth—4 inches to 5 inches—to be out of the way of frost. Generally speaking, however, the tubers are hardy.

IRIS OCHROLEUCA (Whyke).—This species is most erratic in its behaviour, and varies considerably in different districts and soils of a most opposite character. We have, indeed, grown and flowered it quite well in moist, as also singularly dry soils, the latter, however, always well enriched by manure. One thing is certain—it is impatient of removal, and it requires also to be fairly well established before it flowers at all. The root decay points to insect pests, and the roots and soil should be examined for insects of the millipede tribe. If these are present in any number, it is highly probable that they have been boring the rhizomes, the large, fleshy roots of which the plant is composed. Should such exist, your best remedy would be trapping with Potatoes cut in halves or slices and buried an inch or so in the soil, marking their positions so that they may be examined at will. In good health the plant remains green many weeks after flowering. This year, however, the exceptional heat and drought has militated against longevity. If this reply does not meet the case, perhaps you could send a root for our inspection.

THE GREENHOUSE.

CHRYSANTHEMUMS MILDEWED (W. R.).—Your Chrysanthemums appear to be attacked by mildew, and we recommend spraying every week with a solution of an ounce of potassium sulphide in three gallons of water. It is unwise to use the solution stronger than this, as there is some danger of damage to the foliage otherwise.

HEATING SMALL GREENHOUSE (W. H.).—There is no doubt that for a small greenhouse such as that named by you an oil lamp, or, rather, stove, would prove satisfactory. The main point is that it be kept perfectly clean and the house ventilated whenever possible. The best oil, too, must be used. There are various appliances for the purpose, in which a few pipes that do not need any fitting are disposed after the fashion of a radiator, and are heated by a lamp.

TO FLOWER DENDROBIUM FIMBRIATUM (L. F. B.).—*Dendrobium fimbriatum* is always very shy in flowering. The only way to induce it to bloom in a satisfactory manner is, after making its new growth, to keep it as dry as possible and a little cooler in order to give it a period of rest. After this, when returned to its former situation, it should then bloom from the last bulb (not the new one), while it will sometimes flower from very old bulbs, as *D. dalhousianum* does, usually about the month of July.

ROSE GARDEN.

ASHES AS PROTECTION FOR ROSES (J. C. S.).—The ashes obtained by burning garden refuse would answer for protecting Rose bushes during the winter, but coal-ashes or burnt earth, owing to their greater porosity, would be better. Ashes from garden refuse are excellent manure, being rich in potash. The ordinary soil, unless very heavy clay, if drawn up over the stems of the Roses in the form of a mound, makes a good protection.

ROSES FAILING (L.).—Black spot appears to be a disease that when once established becomes difficult to eradicate. We advise you to replant your Roses this autumn after we have had a good rain, and in renewing the beds give a good dressing of basic slag to the lower soil at the rate of 6oz. to the square yard. Have the surface 2 inches or 3 inches of soil removed and burnt, as the spores of the black spot are sure to be present there. Any healthy-looking plants—that is, those whose roots are sound—could be cut back hard and replanted, and the sickly plants replaced with good English-grown bushes grown in exposed fields. The Lyon Rose is badly addicted to black spot, but we should not have expected it upon Mme. Ravary and Mme. A. Chatenay. Certainly Prince de Bulgarie would be superior in growth to Lyon Rose. We can recommend Cissie Easlea as one free from any disease, and it produces such glistening foliage that enables it to withstand these fungoid attacks.

FRUIT GARDEN.

MUSCAT GRAPES SHRIVELLING (Barrington).—Your Muscats are suffering from shanking, and also the Black Hamburgh in a lesser degree. See reply to "Gloucestershire."

PEACH STONES SPLITTING (W. P.).—Lime the soil in which the Peaches are growing. The trees are probably affected with gumming, and it would be well to cut out all the gummed branches and paint the wounds with white paint or with coal tar.

PEACH SHOOTS DISEASED (M. B. R.).—The shoots of the Peach sent appear to be attacked by the Rose mildew, *Sphaerotheca pannosa*. We recommend you to prune away, as far as possible, all those shoots which show the mildew, and to spray the tree thoroughly, while it is dormant, with a solution of copper sulphate, 1lb. in 30 to 35 gallons of water. See that the tree next year is not allowed to suffer from want of water, for that is the main cause, checking it and laying it open to attacks of such fungi as the mildew.

PEARS CRACKING (Down Place).—The Pears are attacked by the disease known as Pear scab. This is due to a fungus called *Fusicladium pyrinum*, which attacks not only the fruit, but the foliage and shoots as well. Your best plan would be to prune out all the shoots that show signs of cracking of the bark (as though they had been injured by frost) and to spray the tree in the winter with copper sulphate at the rate of a pound to twenty-five gallons of water, and afterwards, just before the buds burst and again when the petals have fallen, with Bordeaux mixture at half strength.

APPLE-DISEASED (E. B.).—The Apple is attacked by the fungus *Sclerotinia fructigena*, causing the disease known as brown rot. The fungus attacks the shoots and foliage, as well as the flowers and fruits, though it is more easily seen on the last. Care should be taken to prune out the diseased parts of the tree during the winter. All Apples hanging on the tree should be removed, and the tree sprayed during the winter with a solution of a pound of copper sulphate in twenty-five gallons of water. Spray with Bordeaux mixture just before the buds burst and again after the flowers have fallen.

PEACH ATTACKED BY FUNGUS (E. C.).—Part of the trouble with the Peach is due to shot-hole fungus, part to spraying with an unsuitable compound. Potassium sulphide often causes defoliation of delicate-foliaged plants like Peaches and Nectarines, and we recommend in place of it for these plants ammoniacal copper carbonate in a little water, adding three pints of the strongest ammonia and diluting to forty-five gallons with soft water. We have found this very effective in controlling shot-hole fungus, and it may be used without detriment to the plants sprayed, so long as the spraying is done in dull weather or after dusk.

GRAPE SUPPOSED TO BE BLACK HAMBURGH (H. S.).—The berries were rather badly decayed before reaching us. The variety is certainly not Black Hamburgh, and we agree with you in thinking it is Madresfield Court, and an excellent variety also. The cause of failure in growth is an attack by a miniature species of red spider on the leading shoot of the Vine. It is not at all unusual for this spider to attack the shoots of vigorous young Vines in this way. The only cure is to sponge the parts carefully with a mixture of sulphur and soft soap and water. Mix together half a pint of sulphur with a quarter of a pint of soft soap in warm water, bringing them down to the consistency of thick paint; then add to this half a gallon of water, well mixing together. Sponge the affected parts several times with this mixture until you are satisfied the Vine is clean. Examine the Vine several times for its reappearance, and apply again if necessary.

GRAPES SHANKING (Gloucestershire).—The sample of Grapes sent shows that the Vines are suffering from a disease termed in garden parlance "shanking." This disease is brought about by various causes, all tending to weaken the Vine during its growth of the previous year. It may be the Vine was cropped too heavily the year before, overtaxing its strength. This would bring it about, or it may be that the Vine last year suffered from a severe attack of red spider; or a too heavy application of artificial manure to the roots, causing the destruction of some of them, might be the cause. Cut away and burn all the diseased berries. As soon as the foliage is ripe and has dropped, clear away the top soil of the border until you come to a good mass of roots, and then apply a top-dressing 5 inches deep (after well treading down) of the following soil compost: To a cartload of airy fibrous loam, cut into lumps the size of a quarter of a brick, add three barrow-loads of old mortar rubble, a bushel of quarter-inch bones and the same of bone-meal, also a barrow-load of fresh lime. Mix well together and apply as soon as the roots are exposed. As soon as this top-dressing is laid on the roots, have it covered over to the depth of 12 inches with freshly fallen leaves, these to remain on the border until the first week in April. Crop the affected Vines very lightly next year, and you will find, we think, they will be quite recovered by the following year.

KITCHEN GARDEN.

POTATOES WITH BLACK MARKS (G. A.).—Potatoes not infrequently develop these hollow, black-lined spaces inside when they are allowed to become hot in a store. It may be that they have been put away without drying, or possibly stored in too hot a place. There is also a bacterial disease that attacks Potatoes somewhat in this way, but the symptoms are not quite the same. The tubers certainly do not look nice, but if halved and the black part removed before cooking, it would render them fit for consumption.

BRUSSELS SPROUTS DISEASED (W. T.).—Your Brussels Sprouts are attacked by the disease called club-root, due to the fungus *Plasmodiophora brassicae*. This is best combated by treating the soil with quicklime at the rate of half a bushel to the square rod or rather more, purchasing it in the powder form and spreading it over the ground evenly, digging it in immediately. You will find a short article on this subject on another page.

CATERPILLARS ON BROCCOLI AND SPINACH (B. G.).—The caterpillar sent is that of one of the Cabbage moths or an allied species, and from its habit of feeding on or near the surface and hiding in the soil during the daytime it has earned the name of surface caterpillar. Hand-picking is certainly the most satisfactory way of dealing with the pest, and the only one that can be recommended in many cases. Where plants are not to be used for food, spraying with lead arsenate is the best thing to do.

In some cases success can be obtained by dipping Clover, or something else of which the caterpillar is fond, in Paris green and putting the small heaps near their haunts.

CATERPILLARS ON CABBAGES (W. F. S. H.).—You might try the effect of spraying the Cabbages with water at about 120° or even a little hotter, or with salt water. Either of them would probably reduce the trouble considerably. Phormium tenax often flowers in suitable localities when the plants have attained some size, and not infrequently the seed ripens. We expect you will find flowers in most seasons after this.

MISCELLANEOUS.

VARIOUS QUESTIONS (Berkshire).—Is not the brown appearance of the young fronds of the Maidenhair normal? We do not think anything is wrong with them. The liquid manure may be used when insects are in it and a smell arising from it. It will be rather difficult to prevent flies from breeding in the manure water, but possibly a thin film of paraffin maintained on its surface would effect the purpose.

BOTTLING FRUIT (M. H.).—If the Plums are quite covered with water and no air is allowed to come in contact, the fruit certainly ought not to be discoloured. Before serving up the fruit it will require a certain amount of cooking, but much will depend on the variety and the state of the fruit as to ripeness when bottled. Sugar sufficient to sweeten should then be added. As is well known, sugar can be added at the time of bottling if thought desirable.

GAS-LIME FOR BREAKING UP LAND (S. H. G.).—Gas-lime can rarely be obtained nowadays. We think your best plan would be to get some quicklime (burnt lime or stone lime) and put it in heaps on the ground at the rate of half a bushel to the square rod; cover it with earth, and when it is slaked (in about a fortnight or three weeks), spread it and dig it in this autumn. The weeds and grass should be completely buried, and Twitch, Bellbine and the like removed.

NAMES OF PLANTS.—*A. L. Ford.*—The Belladonna Lily (*Amaryllis Belladonna*).—*Mrs. Logan.*—*Saxifraga sarmentosa*, often known as Mother of Thousands.—*F. K.*—1, *Aster cordifolius*; 2, *A. diffusus*; 3, *A. Novi-Belgii*; 4, *A. N.-B. densus*; 5, *A. Novae-Angliae* Mrs. Raynor; 6, a seedling of *Aster vimineus*.—*H. R. D. THE EDITOR'S TABLE.

Two Beautiful Michaelmas Daisies.—Messrs. T. S. Ware, Limited, of Feltham send flowers of two new Michaelmas Daisies, both of which are superb. The most charming of the twain is *Aster Amellus Arethusa*, a dwarf and freely branched plant with very large, deep rose-coloured blossoms. This received an award of merit from the Royal Horticultural Society a few weeks ago. The other is also a variety of *Amellus*, and is named *Orion*. This has the same habit and large flowers as *Arethusa*, but the blossoms are rich blue in colour. We welcome these as charming additions to the hardy border flowers of late autumn, and feel sure that before long they will be found in nearly every garden in the United Kingdom.

SOCIETIES.

NATIONAL SWEET PEA SOCIETY. ANNUAL GENERAL MEETING.

THIS was held at the Westminster Palace Hotel, London, S.W., on Monday, October 12, Mr. F. W. Harvey in the chair. The secretary, Mr. Henry D. Tigwell, read the notice convening the meeting, and the minutes of the last annual general meeting and of the special general meeting (held in April, 1914), which were approved and signed. It was agreed that the annual report be taken as read. The chairman, in moving its adoption, said that the war had had rather a bad effect on the membership of the society. During the year 145 new members had joined and 72 had resigned, but 50 of those resignations had been received since the war broke out, and there was no doubt that that was mainly the cause of those resignations. New societies to the number of twenty-two had been affiliated, which was double the number of last year, eight had resigned, while a few had not yet paid their subscriptions for 1914. The committee had fully considered the advisability of holding trials next year, and had decided that it was the duty of the society to try to keep things going as well as possible. They had come to the conclusion that Mr. Christy of Roxwell, near Chelmsford, who was willing to undertake the trials, would be the suitable man. He had had considerable experience in the cultivation of Sweet Peas. Major Hurst was unable to undertake the trials next year. In regard to finance, it would be seen that the financial year had not been a very good one for the society. They had had a large number of items to meet, which had been rather extraordinary, if he might say so. To start with, the balance brought forward from last year was about £30 less than in the previous year. In addition to that there were outstanding accounts which had not been rendered at the date when the previous financial year closed, amounting to £37. Those had been paid, of course, out of the current year's accounts. Then it would be remembered that last year Mr. Curtis, their hon. secretary, was compelled to resign the secretaryship, and Mr. Tigwell was elected as a paid secretary with a salary of £50 a year. The committee thought it was quite right and proper to pay Mr. Tigwell his salary every quarter, so that they had had to meet this year the secretarial work of nearly two years. It would be recollected that at the last annual meeting £73 10s. was voted as an honorarium to the late hon. secretary, and in addition to paying that, this year they had paid Mr. Tigwell three quarters' salary, the total amounting to £111. Next year there would only be Mr. Tigwell's salary to pay—one year's salary. Trials expenses this year amounted to £64 5s. 10d., as against £49 10s. 2d. in 1913, which was mainly due to the fact that the seeds were sown in the autumn, this entailing considerable expense. Tenders had been obtained for printing the "Annual" and trials list next year, and a considerable saving would be effected in that direction. It would be seen that there were outstanding accounts with the printers amounting to about £180. This amount the committee proposed to pay with the balance in hand and £150 from the deposit account. That would still leave £50 on deposit. Arrangements had been made to hold the London show on Tuesday, July 13, 1915, that being the only date in July when the committee could obtain the Royal Horticultural Society's Hall. Owing to the war the committee had decided not to incur the expense of a provincial show next year. In conclusion, the chairman proposed that the report and financial statement be adopted. Mr. J. S. Brunton seconded the motion. The report and accounts were unanimously adopted. Votes of thanks to the president, hon. treasurer, Major C. C. Hurst, chairman of committee, and the floral and general committee were proposed, seconded and passed.

Several proposed alterations, additions or amendments to the rules had been sent in, but only two of these were carried. One, a new rule, is as follows: "The committee shall have power to refuse membership to any person." Rule 22 will in future include the words "not more than three varieties" in place of "three varieties."

Miss H. C. Philbrick was unanimously elected president for the ensuing year; Mr. E. H. Christy, chairman of committee; Mr. Reginald Christy, trials superintendent; Mr. E. Sherwood, hon. treasurer; Mr. R. Gluyas, auditor; and Mr. H. D. Tigwell, secretary. The general committee were re-elected with the exception of Mr. Bide, who was not eligible, and the addition of Messrs. T. A. Weston, E. R. Janes, F. W. Harvey and B. Peyman. Mr. H. A. Reekie was added to the list of provincial corresponding members of committee. Balloting for the floral committee resulted in the following being elected: Messrs. R. Bolton, J. M. Bridgeford, C. H. Curtis, A. Hallam, G. Herbert, A. Ireland, T. Jones, H. Smith and T. Stevenson.

READING GARDENERS' ASSOCIATION.

THE second fortnightly meeting of the session was held in the Education Class Room at the College on the 5th inst. The president occupied the chair, and there was a good attendance. The subject for the evening, "How to Keep Mixed Borders Gay from Spring to Autumn," was ably introduced by Mr. H. C. Loader of The Gardens, Ebleigh Park, Reading. The lecturer lucidly explained the method he employs to keep the borders gay at Ebleigh Park with perennials, biennials, annuals and bulbs. Mr. Loader advocated that the borders should be deeply dug and heavily manured, and such perennials planted as Michaelmas Daisies, *Solidago*, *Helenium* in variety, early flowering *Chrysanthemums*, herbaceous *Phloxes*, *Pyrethrums*, *Polyanthuses* and *Dahlias*. The biennials

recommended for planting between the perennials were Canterbury Bells in mauve, white and pink, and Sweet Williams (Pink Beauty); and among annuals Asters (Giant Single and Southcote Beauty), Cosmea, Sutton's New Red Sunflower and Silene (Dwarf Pink). May-flowering Tulips and Daffodils are also freely planted. The successful mode of cultivation, to ensure the borders looking constantly gay and enabling one to cut a bunch of flowers at any time, was dealt with. The animated discussion which took place after the paper had been read showed how much the subject had been appreciated, and a hearty vote of thanks was accorded Mr. Loader for his instructive paper. Exhibits were numerous, and considerably occupied the time of the judges. In the points competition, Class I., Mr. Blackwell received 9½ for Apples, Mr. Goodger 9½ for Pears, Mr. Tovey 9 for Pears, and Mr. Townsend 10 for Pears. In Class II., Mr. F. Haines received 11½ points for vegetables. The *Onlooker* prizes, for three dishes of vegetables, for single-handed gardeners only, were awarded as follows: First, 6s., Mr. F. Haines, gardener to Mr. J. F. Hawkins; second, 3s. 6d., Mr. F. Lamport, gardener to Mr. J. Blandy. Mr. C. J. Howlett was awarded a certificate for a collection of Potatoes and fruit. Non-competitive exhibits were staged by Mr. J. T. Tubb (Peaches), Mr. Wilson (Pears) and Mr. Loader (Asters).

SCOTTISH HORTICULTURAL ASSOCIATION.

THE usual monthly meeting of the above association was held in the hall, 5, St. Andrew Square, Edinburgh, on the evening of October 6. Mr. David King, Osborne Nurseries (the president), occupied the chair, and there was a good attendance. The exhibits were excellent, and included the following: Collection of excellent vegetables from the lecturer of the evening, Mr. D. M. Welsh, The Gardens, Spean Lodge, Spean Bridge; a splendid exhibit of about sixty varieties of early Chrysanthemums of the different sections and Antirrhinum *Nelrose*, sent by Messrs. Dobbie and Co., Edinburgh; a comprehensive exhibit of splendid Apples from Mr. W. G. Pirie, The Gardens, Dalhousie Castle, Bonnyrigg; Chrysanthemums and about eighteen varieties of Potatoes from Miss Burton, Polton; dried Potatoes, &c., from Mr. G. P. Berry of the Board of Agriculture, London; and flowers of *Cobæa scandens* (grown in the open) from Mr. Charles Comfort, The Gardens, Broomfields, Davidson's Mains. In the absence of Mr. Welsh, the lecturer of the evening, his paper was read by the secretary. It was entitled "Vegetables for the Western Highlands," and was a valuable contribution on the subject, dealing fully with the conditions existing in this rather difficult district and detailing the best varieties. As was indicated in the paper, the weather conditions are troublesome, as at Spean Bridge the average rainfall was 67 inches. Mr. Welsh stated that about four months covered the period of growth for the vegetables. The lecturer also gave figures to show the range of temperatures, and recounted the difficulties experienced under such conditions.

SCOTTISH TRIAL OF GARDEN DAHLIAS.

FOLLOWING upon the great trial of Dahlias held during the season of 1913 by Mr. Reginald Cory at Duffryn, Cardiff, it was decided last spring to conduct a trial on somewhat similar lines in Scotland, so as to ascertain whether the results obtained at Cardiff would be maintained in the North. The National Dahlia Society accepted the offer of Mr. Robert Fife of Messrs. Dobbie and Co., Edinburgh, to conduct the trial in the firm's grounds there. The varieties under trial were, as far as possible, the same as those grown at Cardiff in 1913, and each variety was represented by two plants.

Those who contributed to the Scottish trial, and who sent all plants free of charge, were Messrs. R. H. Bath, Limited, Wisbech; Messrs. J. Cheal and Sons, Crawley; Mr. J. A. Jarrett, Anerley (an amateur); Mr. S. Mortimer, Farnham; Mr. J. B. Riding, Chingford; Messrs. W. Treseder, Limited, Cardiff; Mr. Charles Turner, Slough; Messrs. T. S. Ware, Limited, Feltham; Mr. J. T. West, Brentwood; and Messrs. Dobbie and Co., Edinburgh. With three exceptions the plants were sent in quite early in the season, and were grown into large plants before the planting-out time arrived. The varieties on trial numbered 458 (in addition to many seedlings), grouped as follows: Cactus, 113; bedding Cactus, 11; *Pæony*-flowered, 124; Pompons, 42; decorative, 45; *Collarette*, 103; show and fancy, 47; singles, 36; with some other sections represented by fewer varieties. The plants, on the whole, made very satisfactory growth, and, as a rule, were in full flower at the time of inspection. The moist and warm weather, however, had forced them into new growth, which more or less hid the flowers in the case of some varieties of well-known decorative value.

The inspection took place on Monday, September 14, and the following gentlemen were appointed to make the awards from a garden decorative point of view: Mr. J. E. McHattie, Superintendent of Parks, Edinburgh; Mr. J. Whitton, Superintendent of Parks, Glasgow; Mr. Matthew Campbell, nurseryman, Blantyre; Mr. John Smellie, nurseryman, Busby; Mr. D. Kidd, gardener to Lord Elphinstone, Carberry Towers, Musselburgh; and Mr. J. Highgate, gardener to the Marquis of Linlithgow, Hopetoun House, South Queensferry. The following varieties were granted three marks, which indicate the highest quality for garden decoration:

Collarette Dahlias.—Anerley Gem, Annan, Carl Bechstadt, Deveron, Doon, Esk, Fascination, Forth, Henri Farman, Holyrood, Inchmarnock, Lugar, Leader, Liffey, Monach, Nethan, Ouse, Parrot, Purity, Queen Bess, Queen Mary, St. Abbs, Skerryvore, Tay, Thames, Tweed and Tuskar.

Cactus Dahlias.—Amos Perry, Eclair, Firefly, Ivernina, Mrs. Freeman Thomas, Mrs. F. Grinstead, Mrs. F. Paton,

Mrs. J. Barker, Mrs. Landale, Nimrod, Salmon Queen, Star, Vivid, Vulcan and Westhall Scarlet.

Pæony-Flowered Dahlias.—A. Roosevelt, Codsall Gem, Europa, Gen. Botha, Germania, Hortulanus Budde, H. J. Lovinck, Kakadee, Liberty, Lord Milner, Mafeking, Mozart, Paul Kruger, Pretoria, Primrose Queen, Queen Wilhelmina, Reynolds, Salome, Sparkler, Splendour and Weber.

Pompon Dahlias.—Blush Gem, Crusoe, Daisy, Evelyn, Glow, Ideal, Ivy, Little Beeswing, Little Frank, Little Mary, Tommy Keith and Tommy Laing.

Single Dahlias.—Althea, Beacon, Cardinal, Grenadier, Mrs. W. Merry, Mr. E. D. Till, Mikado, Owen Thomas, Rosemary Bridge and Willie Fife.

Show Dahlias.—Duchess of York, Excellent, Prince Bismarck, Prince of Denmark and William Rawlings.

Decorative Dahlias.—Brentwood Yellow, Delice, Firefly, Jeanne Charmet, K. A. Victoria, Lorely, Loveliness, Mont Rose, Offenbach, Princess Juliana, Sulphurea and W. Goethe.

Other Sections.—Bedding varieties: Argos, Amanda, Barlow's Bedder, Charlotte, Gluckhauf and Marianne. Cosmea-flowered: Crawley Star. Mignon or Tom Thumb: Agnes, Jules Closson, Lancer and Pembroke. Anemone-flowered: Mons. Ch. Dupont.

TRIALS OF EARLY FLOWERING CHRYSANTHEMUMS.

IN addition to the extensive trial of early-flowering Chrysanthemums which is this year being conducted by the Royal Horticultural Society in their gardens at Wisley, Surrey, a very large trial of the same class of plants is being made by Messrs. Dobbie and Co. of Edinburgh. In addition to their own stock they have purchased from various sources all the varieties of early Chrysanthemums which they could secure. Many of the plants were somewhat small when received, and the planting, which was made in the early part of May, was irregular on this account.

These Chrysanthemums were all planted in batches of each colour, so that, when the adjudication was made, comparison would be much easier. As was to be expected, the growth of the different varieties was very irregular, ranging from about 1 foot to 4½ feet in height. The period of blooming, too, was quite as varied as the height of the plants. The first flowers appeared early in August, while the later varieties will not come into bloom until well on in the present month and on this account are not suitable for northern cultivation.

It was thought advisable to have the collection inspected about the middle of the season, and this took place on September 22, the following gentlemen acting on the adjudication committee: Messrs. W. H. Massie of Messrs. Dicksons and Co., Edinburgh; John Phillips, Granton Road Nurseries, Edinburgh; John Alexander, The Gardens, Niddrie, Craigmillar; and William Galloway, gardener to the Earl of Wemyss, Gosford, Longniddry. It may be added that the foregoing all occupy prominent positions in the Scottish Horticultural Association.

The varieties under trial were as follows: Japanese early-flowering, 190; but of these 62 were not in bloom at the date of inspection. Pompon varieties, 39; of these 10 were not in bloom at the date of inspection. Single varieties, 99; of these 9 were not in bloom at the date of inspection.

The following awards were made from the garden decorative point of view:

EARLY CHRYSANTHEMUMS.

Best white.—Artemis, Cranford White, Doris Peto, Tuckswood Early and White Countess. Second best white.—Auguste, Framfield Early White, Grosvenor, Hermine, La Neva, Market White and Pluie d'Argent. Best creamy white.—Cream Perrier and White Massé. Second best creamy white.—Perle Chatillonaise. Second best primrose.—Ethel. Best pale yellow.—John Bannister. Best deep yellow.—Carrie, Elstob Yellow, Horace Martin, Leslie, Champ d'Or, Maggie, Miss B. Melville, Orion and Polly. Second best deep yellow.—Curtis Martin. Best blush.—Cynthia, L'Yonne and Normandie. Second best blush.—Blush Beauty. Best rosy pink.—Lillie and Mme. C. Pereire. Second best rosy pink.—Calliope, Dolly Reeves, Dorothy Ashly, James Bateman and Mme. Marie Massé. Best rosy lilac.—Improved Massé. Best chestnut crimson.—Almitante and Mrs. Willis. Second best chestnut crimson.—George Bowness. Best crimson.—Crimson Diana, Crimson Polly, Goacher's Crimson, Kuroki and Mrs. W. Sydenham. Best crimson scarlet.—Wells' Scarlet. Best terra-cotta.—Abercorn Beauty, Orange, S. F. Richmond and Verona. Best bronze.—Bronze Goacher. Second best bronze.—Mrs. J. Fielding and Nina Blick. Best orange bronze.—Diana and Harrie.

POMPON EARLY CHRYSANTHEMUMS.

Second best white.—La Vièrge. Best yellow.—Craigmillar. Second best yellow.—Flora and Mignon. Second best bronze.—Mrs. E. Stacey. Second best pink.—J. B. Duboir. Best blush.—Mr. Selby. Best crimson.—Little Bob. Second best crimson.—Fred Pele and Toreador.

SINGLE EARLY CHRYSANTHEMUMS.

Best white.—Marion Bannister and White City. Second best white.—Walton Bradbury. Best yellow.—Ada Nice, Brightness and Joan Carter. Second best yellow.—The Moon. Best orange.—Wells' Pride. Second best bronze.—Eric. Second best salmon.—Canada. Second best terra-cotta.—Dr. Ingram and Holmthorpe. Second best blush.—Brazier's Beauty and Daisy Bell. Best pink.—John Woolman and Pink Gem. Second best pink.—Early rose. Best purple rose.—Dorothy. Second best crimson chestnut.—Alexander and A. J. Foster. Best crimson.—Dazzler. Second best crimson.—Kate Westlake, Merstham Glory and Ruby. Second best fiery red.—W. A. Cull.

NATIONAL DAHLIA SOCIETY.

ANNUAL CONFERENCE.

ON Thursday evening, the 15th inst., the above society held its annual conference at Carr's Restaurant, Strand, when Reginald Cory, Esq., occupied the chair. In the absence of the secretary, Mr. Charles H. Curtis ably fulfilled his duties. In opening the meeting, Mr. J. Cheal introduced the chairman, who expressed his pleasure at presiding, although it was mitigated by the recollection of the recent death of their chairman, the late Mr. George Gordon, a great friend of the society, and in whose death horticulture generally had lost a sympathetic leader. The members this year had experienced some disappointment, for the conference was originally intended to have been held at the White City. War trouble caused it to be removed to the Crystal Palace, then to the Royal Horticultural Society's Hall, and finally they found a refuge at Carr's, where he was glad to welcome them. He then called upon Mr. J. Stredwick to read the first paper, which was entitled "The History of the Dahlia."

Mr. Stredwick then related a few facts connected with the early history of the flower. There was practically nothing new or interesting in his communication, which consisted of a few historical facts admittedly drawn from the writings of the late Richard Dean. Then came a personal record of the reader's experience, chiefly in regard to the Cactus Dahlia and its progress. In the discussion that ensued Mr. Harman Payne pointed out that in 1889 the National Dahlia Society celebrated the centenary of the introduction of the Dahlia into Europe by holding a conference at the Crystal Palace. On that occasion Mr. Shirley Hibberd contributed a paper on the history of the Dahlia, which, with his great literary skill and capacity for research work, had never been surpassed, and remained to this day, in spite of all subsequent attempts by other less competent writers, the most authoritative work on the subject. This paper was printed *in extenso* in the National Dahlia Society's Schedule for 1890, and nothing that later writers had done had contributed to a fuller knowledge of Dahlia history. Mr. Payne ridiculed the suggestion that the Pompon Dahlia was known in 1808, and said that independent and original research among the records failed entirely to establish the fact of its existence until at least fifty years later. He also raised a query as to the employment of the mongrel English word "Collarette" for the French word "Colletterie," and severely challenged the use of the word "Pompon" as applied to the small-flowered Cactus Dahlia. Several speakers followed, but their remarks were chiefly confined to cultural questions relating to the Cactus and Collarette sections, Mr. Wyatt, Mr. J. T. West and the chairman taking part. Mr. Stredwick replied.

The next paper was entitled "The Dahlia as a Decorative Plant for Parks and Gardens," and was received with appreciation by the hearers. Then came a paper by Mr. Harrison Dick on "The Dahlia in America," read by Mr. Curtis. In this there was a good deal of interesting information concerning the historical aspects of the Dahlia in the States and the local Dahlia societies' work there; also difficulties of culture and details concerning the cut flower trade. This paper also raised several points for an interesting discussion, in which many speakers took part.

Votes of thanks to the gentlemen who had contributed papers and to those who took part in the discussions were accorded, also one to the chairman for presiding. This brought the proceedings to a conclusion.

CHELMSFORD AND DISTRICT GARDENERS' ASSOCIATION.

THE first meeting of the winter session was held in the East Anglian Institute of Agriculture on Friday, October 2. Mr. C. Wakely presided, and about forty members were present. Mr. Pugh of Messrs. Carter and Co. of Raynes Park gave a very interesting and instructive lecture on "Lawns." The lecturer explained that not only is a lawn an asset to any garden, but of late years had become of great importance on account of games, such as bowls, croquet and tennis, being played upon them. Practical operations, such as seed-sowing, cutting, rolling and levelling, were fully explained by the lecturer. Specimens of seeds and weeds, &c., were shown, and the lecture was illustrated by a fine set of lantern slides. At the conclusion of the discussion a hearty vote of thanks was accorded Mr. Pugh for his excellent lecture.

WARGRAVE GARDENERS' ASSOCIATION.

AT the last meeting of the members an able paper on "Michaelmas Daisies" was given by Mr. P. Wiseman of Messrs. Waterer, Sons and Crisp's nurseries at Hare Hatch. He gave full directions for planting in the border and the best method of arranging them for effect. The shorter varieties were recommended for pot culture, as it deserved. In tubs, too, they made a grand show. A good discussion ensued, and Mr. Wiseman was thanked for his address. Messrs. Waterer and Co. staged a fine exhibit of Michaelmas Daisies, and were thanked for so doing. Mr. Pope was awarded a cultural certificate for a nice group of *Cypripediums*, and Mr. Cox was highly commended for a dish of Peaches.

Brighton, Hove and Sussex Horticultural Society.—It is with much regret that the committee of the above society have decided to abandon the Chrysanthemum show arranged for November 3 and 4, also the lecture on November 19.

THE GARDEN.

No. 2241.—VOL. LXXVIII.

OCTOBER 31, 1914.

NOTES OF THE WEEK.

Medicinal Plants in England.—In Leaflet No. 288, just published, the Board of Agriculture draw attention to the fact that, owing to the war, there is likely to be a shortage of medicinal plants next year. They rightly point out that, in the ordinary way, a few pounds of dried herbs are only disposed of with difficulty; but next year, owing to the shortage, small quantities will doubtless be very welcome to buyers. The leaflet gives the names and cultural details of the herbs mostly in demand, and we hope to publish it in subsequent issues.

An Interesting Tropical Orchid.—The plant illustrated on this page is a native of Madagascar, and bears the somewhat unwieldy name of *Angræcum sesquipedale*. It is one of the most interesting of winter-flowering Orchids, its ivory white blossoms usually opening during November, December and January. Their most remarkable feature is the spur, which often attains a length of from 10 inches to 18 inches. For its successful cultivation this Orchid needs a stove-house where a winter temperature of 60° Fahr. can be maintained. For a rooting medium it should be given a mixture of charcoal, peat and sphagnum moss. It is a plant that deserves to be more widely cultivated where facilities exist for providing the proper temperature.

An Attractive Plant for the Rock Garden.—In *Corydalis Wilsonii* we have a valuable plant for the rock garden. This beautiful Chinese species, of recent introduction, commenced flowering early in the summer, and is still bearing many spikes of its bright yellow flowers, which stand up in a very graceful manner above its attractive, Fern-like foliage. It should be planted in well-drained soil, and if given the protection of a large rock, so much the better, as excessive moisture during the winter is its chief enemy. It is readily raised from seed, and will, when it becomes better known, be found in all gardens where choice flowers are grown.

A Good Autumn Rock Garden Plant.—Of the trailing or prostrate habited sorts flowering in autumn, the Japanese *Sedum Sieboldii* is certainly one of the most distinct and ornamental, and as such merits general cultivation. It is, however, more frequently seen as a pot-grown window

plant or in the greenhouse, and the growers of it in such places are surprised to learn that it is quite hardy. As a good rock garden subject it is worthy of special thought, and, given a well-exposed and sunny position, the heads of rosy coloured flowers are often accompanied by highly coloured leafage. At other times the latter is of glaucous hue, well separated from others of its class. There is a variegated form less good in general effectiveness.

Experiments with American Gooseberry Mildew.—In the annual report of the horticulture branch of the Board of Agriculture considerable space is devoted to work that has been done during the past year in connection with American Goose-

and one that ought to be extensively grown, is Geum Mrs. Bradshaw. Some young plants that we have are still producing their scarlet flowers freely, and have not been without blossoms since early June. Owing to the fact that they are produced on long, branching stems, they are ideal for cutting, and, when arranged with any kind of white flowers, never fail to elicit praise from visitors. This Geum will produce seed freely if allowed to do so, and the seedlings come true and retain the good qualities of their parent. The plant is not fastidious as to soil, though deep cultivation and liberal manuring are appreciated. Can any reader name a more useful hardy perennial than this?

New Garden Suburb in Glasgow.

—THE GARDEN has always taken a warm interest in garden city and suburb schemes and has done much to promote such enterprises. We are pleased to hear of a new garden suburb for Glasgow which was inaugurated on October 17, when the Hazelwood one was the scene of an interesting ceremony — that of switching on the electric current which is to supply lighting, cooking and heating for this new garden suburb. Hazelwood is in a capital position, adjoining Bellahouston Park and the tramway terminus of Dumbreck, and it is likely to become a popular place.

Mr. W. G. Pirie, Dalhousie Castle Gardens.—We learn with pleasure that Mr. W. G. Pirie, Dalhousie Castle Gardens, is to be the new president of the Scottish Horticultural Association. Mr. Pirie is in the first rank of Scottish gardeners, as is attested by the gardens of which he has charge

and his many successes in leading classes at the principal Scottish shows. His employer, Mr. C. W. Cowan, is one of the best supporters of horticulture in Scotland, and Mr. Pirie does full justice to the many choice things which are placed in his charge. A son of the garden, Mr. Pirie is a general favourite with his brother-gardeners, and they will doubtless receive the appointment with acclamation. He has long taken a lively and practical interest in the affairs of the Scottish Horticultural Association and has performed many services on its behalf. Mr. Pirie will form an excellent successor to the present able president, Mr. David King, Osborne Nurseries, Murrayfield, Edinburgh.

ANGRÆCUM SESQUIPEDALE, AN INTERESTING WINTER-FLOWERING ORCHID FROM MADAGASCAR

berry mildew. A number of experiments have been carried out in different parts of the country by spraying with lime-sulphur and other washes, but the results obtained have not been entirely satisfactory. In summing up the experiments it is pointed out that the prompt removal and burning of the affected tips of shoots has, up to the present, proved the best method of dealing with the disease. Other important investigations carried out by this branch during the year relate to the pollination of fruit trees and the wart disease of Potatoes.

A Good Scarlet-Flowered Perennial.—One of the most useful herbaceous plants in the garden,

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Shirley Poppies in October.—I was much interested in the note in your issue for last week on Shirley Poppies flowering at Hampton Court in October. When at Kew about a fortnight ago, I noticed a long stretch of border at the back of the rock garden filled with flowering plants of Virginian Stock. The seed of these had evidently been sown in July, and the effect was certainly very charming. This late sowing of annuals might be much extended, and our gardens in the autumn considerably enriched thereby.—A. B. ESSEX.

When to Plant Tulips.—I am disappointed that Mr. Dunn has not vouchsafed your readers an explanation for the remarkable advice he

ing spray of *Buddleia variabilis veitchiana*, which I consider is one of the best shrubs that blossom in August. It is an exceedingly easy plant to grow, thriving in almost any kind of soil so long as it is well manured, and it quickly makes a noble bush 8 feet to 12 feet high. I find it does much the best when pruned back hard each spring, just before the leaf-buds burst. Treated in this way it will make new growths nearly six feet long during the summer, and in August each is terminated by a beautiful raceme, a foot or more long, of Heliotrope-coloured flowers. Side shoots near the top also blossom, and keep up the display for several weeks. Bumble-bees and also butterflies are exceedingly fond of the flowers. I strongly advise anyone who appreciates autumn-flowering shrubs to plant this *Buddleia* during the present autumn or coming winter.—J. D. M.

The Value of Hardy Heaths.—THE GARDEN has often insisted on the value of the hardy Heaths,

A FLOWERING SPRAY OF *BUDDLEIA VARIABILIS VEITCHIANA*, A BEAUTIFUL HARDY SHRUB FOR AUTUMN EFFECT.

gave them as to the time for planting Darwin Tulips. Mr. J. Duncan Pearson's contribution is interesting, but, unfortunately for him, a short time since I received the bulb catalogue of Messrs. J. R. Pearson and Sons, an old-established firm of high repute, of which, I believe, he is a member. Therein I read on page 14 the following: "We ourselves grow some three acres of Darwin and other late Tulips, and produce finer bulbs than we can procure from anywhere else. Plant in October or November," &c. So out of the mouth of Mr. Pearson's own firm's catalogue I prove my case for late planting. Could better evidence be adduced in favour of it when such good bulbs are obtained by it?—OBSERVER, Weybridge.

A Useful Autumn-Flowering Shrub.—I have read with interest the notes and articles that have appeared in THE GARDEN at different times on hardy shrubs that flower in the autumn. I am sending you herewith a photograph of a flower-

ing spray of *Buddleia variabilis veitchiana*, which I consider is one of the best shrubs that blossom in August. It is an exceedingly easy plant to grow, thriving in almost any kind of soil so long as it is well manured, and it quickly makes a noble bush 8 feet to 12 feet high. I find it does much the best when pruned back hard each spring, just before the leaf-buds burst. Treated in this way it will make new growths nearly six feet long during the summer, and in August each is terminated by a beautiful raceme, a foot or more long, of Heliotrope-coloured flowers. Side shoots near the top also blossom, and keep up the display for several weeks. Bumble-bees and also butterflies are exceedingly fond of the flowers. I strongly advise anyone who appreciates autumn-flowering shrubs to plant this *Buddleia* during the present autumn or coming winter.—J. D. M.

The Value of Hardy Heaths.—THE GARDEN has often insisted on the value of the hardy Heaths,

Daboecias. August—*Cinerea*, *c. atrosanguinea*, *c. alba*, *Tetralix*, *vagans*, *stricta*, *ciliaris*, the three *Daboecias*, *vulgaris*, *Hammondii*, *Alportii*, *Searlii* and *flore pleno*. September—*Cinerea*, *c. atrosanguinea*, *Tetralix*, *vagans*, *ciliaris*, the three *Daboecias*, *vulgaris*, *Hammondii*, *Alportii*, *Searlii* and *flore pleno*. October—*Tetralix*, *vagans*, *ciliaris*, the three *Daboecias*, *vulgaris*, *Alportii*, *Searlii* and a few plants of *mediterranea hybrida*.—MACAULAY MORT, *Black Firs*, *Fulmer*, *Bucks*.

Wanted: Mildew-proof Roses.—Rose-growers who are readers of THE GARDEN naturally look with some expectation for the October Rose Number, and never fail to find much that is interesting and profitable. Personally, I have been particularly interested by the conspectus of the *Pernetiana* section by your contributor "E. E. F." My own great trouble is mildew, which, in my sheltered garden, has this year been a great scourge. It is not so much that it impairs the vitality of the trees or the beauty of the flowers as that it destroys the beauty of the foliage and gives a generally unwholesome look to the Rose-beds. It is high time, surely, that the raisers of new Roses were giving their attention to the creation of a race of Roses immune from mildew. Possibly they are; but in that case the success so far has been small. Would it not be possible to get from those of your readers experienced in Rose-growing a list of Roses which they consider (1) absolutely mildew-proof, (2) possessing good resistant power, though not absolutely immune, and perhaps (3) fairly free from the disease when grown in favourable circumstances? If I could secure a fair number of immune, or nearly immune, varieties, offering a good range of colour, I should eliminate from my garden those most susceptible to the disease, much as I should regret parting with many of them. I have already turned out all the old *Crimson Damasks*, which grew plentifully in my borders, and I am also getting rid of my *Crimson Ramblers*, though they flower in their season uncommonly well. A Rose which I have found to be absolutely mildew-proof is *Boule de Neige*, the value of which as a border Rose does not seem to be sufficiently appreciated. I notice that some correspondents of THE GARDEN find *Grüss an Teplitz* predisposed to the disease, whereas with me it is one of the least infested. General Macarthur is another Rose with good resistant powers. *Juliet* has the foliage pretty free from the disease, but the thorns are badly infected. It is the fresh new growth of Rose foliage in August and September that is so liable to mildew, the mature foliage produced earlier in the year being free of the pest. My practice is to cut off the foliage infected and burn it; but this means sacrificing a deal of bloom. As for washes and sprays, I have little faith in their efficacy. Anyhow, the spraying of all my Roses once a fortnight, as recommended in the counsel of perfection, is a task for which I have neither time nor energy. I should be grateful, therefore, to any of your readers who could put me on to good Roses little predisposed to mildew. I am afraid the recent creations of rosarians are too exquisite for this mildewy world.—SOMERSET. [We shall be pleased to receive particulars of mildew-proof Roses, or those that are nearly so, from other readers. We have found the following very free: *Duchess of Wellington*, *General Macarthur*, *Lady Alice Stanley*, *Miss Cynthia Forde*, *Arthur R. Goodwin*, *Grüss an Tep'ltz*, *Jessie*, *Château de Clos Vougeot* and *Zephyrine Drouhin*.—ED.]

THE GLADIOLUS IN AUTUMN.

AUTUMN is a time of special importance in the life-history of the Gladiolus, for it is according to the treatment the corms receive whether they shall become decadent or continue in a condition of health and vigour. As long as the foliage remains green, it is an indication that the corms are not yet mature, and therefore to lift the latter at that stage is not correct treatment. At the same time, in late localities it may be essential, on account of the season, to lift them before growth is completed, and the plan in such cases is to lift the corms with as much soil attached to the roots as possible, and to lay them in a cool structure till the foliage turns yellow. That is the way I proceed with all our stock, which at the time of removal from the ground still retains a measure of greenness in the leaves, and it is very noticeable how the large corms and the small ones nestling at their bases continue to swell after lifting.

Yearling seedlings, as well as the small corms of a year's growth, do much better when not lifted, but protected by some suitable covering during the winter. In many parts of the country this plan might be pursued without the least danger of losing the plants, more especially when the newer strains are grown, these proving much hardier than the old *gandavensis* section, and they are at the same time less subject to disease. They are also, many of them, far better adapted to garden decoration, though less desirable from the florist's point of view. If one is careful of the "spawn," or young bulbs which are formed at the base of the corms, in some instances in very great numbers, a supply of fresh, vigorous corms is quite easy to provide, and if to these seedlings are added from seeds saved at home, a very interesting addition to their number is secured. The seedlings may be of no use commercially, but some of the varieties seem to reproduce themselves fairly well from seeds, and, anyhow, from a good selection it is rare to find a seedling that has not some valuable qualities.

At the time of writing, Peace, an improved form to all appearance of the very old Shakespeare, is still beautiful. I grow Gladioli in conjunction with other plants, as well to provide colour before they bloom as when they are past. In this instance *Cuphea strigillosa* (Cyanea) is the supernumerary Dawn, a lovely form just over, was associated with a mauve Viola. The scarlet Mrs. Francis King has *Nepeta Mussinii*, and the loveliest of all, Halley, was associated with common Cornflower and *Campanula pyramidalis*. The last named is a very free seeder, and I have this autumn obtained thousands of seeds of this variety. I must not omit to point out how small corms usually provide flowers very late in the year, and these and seedlings are still promising many spikes in addition to those which are open. By cutting the latest and opening them in a heated structure or a room, a very late supply of flowers is possible.

A gardener recently was anxious to know how seedlings were treated. My plan is to sow seed thickly in ordinary cutting-boxes early in the year, transplanting the seedlings into the garden about the end of May, in the same way as Onions are raised and transplanted.

R. P. BROTHERSTON.

THE HEARTSEASE OR PANSY.

ALTHOUGH the common Heartsease that we find growing wild in our corn-fields has been known for a great many years and is to be found illustrated in some of the old herbals, it was not until about a century ago that any serious efforts were made to improve it as a garden flower. The old illustrations referred to show us ragged-looking plants bearing a few miniature flowers, the sepals of which are much longer than the petals. Comparing these illustrations with the beautiful symmetrical Pansies that adorn our gardens to-day, we get a valuable object-lesson in what can be done by intelligent and enthusiastic perseverance on practical, rational lines. For the ancestors of our modern garden Pansies we are indebted to Lord Gambier and his gardener, Mr. Thompson, who, at Iver, in Buckinghamshire, about the year 1813, began experimenting with the common wild Heartsease, and who, during the following quarter of a century, raised varieties which at that time were rightly regarded as wonderful improvements on the type.

In the eighties of the last century, the florist's Pansies, as the best of the large-flowered varieties were termed, were at their zenith of fame; but since then their popularity has waned considerably, though everyone who sees them well grown cannot fail to be charmed with their quaint, cat-faced flowers of almost circular outline. It is in the way of form and size that these modern giants differ mainly from the original Heartsease, the flowers of which, as I have already pointed out, are small and ragged-looking, and to-day scarcely worth a passing notice. The introduction of the hardier and more continuous flowering garden Viola or Tufted Pansy undoubtedly did much to oust the large-flowered Pansies from their erstwhile proud position, particularly in the hot Southern gardens, where they always, more or less, lived on sufferance and seldom appeared to be really happy. Later still the miniature Tufted Pansies, or Violettas as some are pleased to call them, were introduced, and perfect gems they are, particularly when well placed in a cool nook in the rock garden. Thus, in briefly tracing the history of the garden forms of Heartsease, we see that from a small flower those of large dimensions were evolved; then, with the aid of other foreign species, smaller-flowered, tufted plants were secured, and, from these, smaller flowers and more diminutive habit again. This, to the unknowing, may seem a reversion, but one has only to compare the miniature Tufted Pansies of to-day with the wild Heartsease to see that everything else which is good has been retained.

The cultivation of all types of the modern Pansy is the same; but, as will already have been inferred, the Tufted Pansies, owing to their more vigorous constitution and free-flowering propensities, give us the best returns, particularly in the Southern Counties. In the more moist and cooler Northern climate, the large-flowered varieties are still grown to perfection, Scottish gardeners especially excelling in their cultivation. In the Western Counties of England, too, these Pansies thrive apace, but it is seldom that one finds them looking really happy in the London district. The Tufted Pansy and its miniature counterpart, however, will flourish almost anywhere if a few cultural essentials are

provided. The most important of these is undoubtedly the soil. Dry, sandy soil on the one hand and heavy clay on the other are equally bad for our Pansies, and a good deal of ingenuity is called for to make them at all suitable. By heavily manuring the sandy soil with well-decayed cow-manure, vegetable refuse and, if possible, some clay, or, indeed, anything that will tend to hold moisture and provide a cool rambling place for the roots, we can do much to enable us to grow at least the Tufted Pansies. Clay soil needs to be made porous, and to this end plenty of long stable manure, burnt earth, sand, old mortar and leaf-soil should be dug in and well mixed with the soil in autumn, the whole surface being left rough for the winter frosts to pulverise. Between these two extremes of soil we get many kinds that, by intelligent cultivation, can be made suitable for our Pansies. We must, however, always bear in mind that slight shade from scorching midday sun and, more important still, a cool medium for the roots, with plenty of humus as food, are essentials.

There are two ways of increasing the large-flowered Pansies—by means of cuttings and by seed. The former is the method usually preferred, owing to the fact that seedlings rarely come true. Both these methods can be applied to the Tufted Pansies, which may also be divided during the early days of spring. Cuttings made from young shoots are usually planted in cold frames in September and October, and seeds are also sown in July or early August, though some prefer to sow seed in January and February. The plants from seed sown in August will flower early the following spring, while those raised early in the year will flower later. Planting is also successfully carried out at two periods, viz., autumn and spring. Where the plants are ready and the soil is of a sandy, well-drained character, autumn planting has much to commend it; but where clay predominates, or excessive atmospheric moisture is experienced, the work is best left until the spring, the first week in April being a good time to get the plants into their flowering quarters. On their value in the garden there is no need to dilate. Few plants will give such a continuous and pleasing display over so long a period as the Tufted Pansies, and the purposes to which they may be put are many. There are numerous named varieties now obtainable, and all the following can be relied upon to do well under ordinarily good conditions: Large-flowered Pansies—Bobby Harper, white; Annie D. Lister, yellow; Colonel M. R. G. Buchanan, brown, yellow and violet; Lord Roberts, yellow and carmine; W. B. Child, yellow and purple. Tufted Pansies—A. J. Rowberry, pale lemon yellow; Archie Grant, deep purple; Bullion, deep golden yellow; Christiana, pale sulphur; Countess of Hopetoun, white; J. B. Riding, purplish mauve; Jubilee, dark purple; Lavender Queen, pale purplish mauve flowers; Maggie Mott, lavender blue, very free flowering; Marchioness, white; Moseley Perfection, deep yellow; Mrs. Chichester, sulphur white, edged deep blue; Royal Sovereign, golden yellow; and W. H. Woodgate, pale lavender blue. Miniature Tufted Pansies—Cynthia, bluish lilac; Diana, primrose yellow; Eileen, deep blue, yellow eye; Estelle, pure white, very small; Lavinia, bluish lavender; Robbie Jenkins, white, suffused yellow on lower petals; and Thisbe, pale bluish with yellow eye. These lists are by no means exhaustive, but all the varieties mentioned are good.

B. B.

THE BEST HARDY BROOMS

DURING the month of May, when most spring flowers are at their best, it is difficult to imagine a more beautiful sight than a deep railway cutting, the banks of which are clothed with the semi-pendent, golden-wreathed shoots of the common Broom, *Cytisus scoparius*. On waste land, wherever the soil is poor, this beautiful wild shrub will be found, usually in clusters of varying size, sometimes scarcely exceeding a yard in diameter and at others extending for many times that distance.

THE WHITE SPANISH BROOM (*CYTISUS ALBUS*).

It is from this grouping of Nature that we should take a lesson when attempting to cultivate shrubs of this kind; isolated bushes, beautiful as they are, do not give us the same bold effects as colonies of three or more, according to the size of the garden and the space to be filled. Although the wild Broom is a very beautiful plant, there are a number of others, some varieties, some species and others hybrids, that are perfectly hardy in our gardens. These vary in dimensions from almost prostrate-growing kinds, suitable for the rock garden, to others that form small trees; hence their value for different positions in the garden can scarcely be over-estimated.

Soil and Cultivation.—To those whose gardens are composed mainly of sand or very poor soil, these hardy Brooms are of the greatest value. The more starved they are, the better they seem to flower, although growth is not, perhaps, quite so rapid as where the diet is rather more generous. For the wild garden, where there are rugged banks to clothe, or large, irregular-shaped beds to fill, no better plants can be found. It is, however, always advisable to keep them clear of weeds until they have attained goodly dimensions, so that they are able to fight for themselves in the great battle of the survival of the fittest. Young plants in pots should be purchased, as

Brooms resent serious disturbance of their roots. Most of the species can be raised from seeds sown in pots or boxes of sandy soil in autumn or spring, but the varieties and hybrids are usually propagated by means of cuttings. This, however, is work for the nurseryman to undertake.

Pruning.—Young plants should be cut back rather severely for the first year or two after planting, so as to induce them to form a bushy habit; but once the foundation is laid for this, little use need be made of the knife. The purple-flowered Broom, *Cytisus purpureus*, however, differs from others in this respect, as it benefits considerably by being cut back nearly to the ground-level each year after flowering, young

shoots springing from the base to take the place of those removed. As already stated, there are many kinds of Brooms that are suitable for our gardens. The best are included in the following list:

Cytisus ætnensis is the Mount Etna Broom and one of the latest to flower, being at its best usually in August. It eventually makes a small tree with pendulous, rush-like shoots, whence its golden flowers are produced in abundance.

***C. albus*.**—This is the white Spanish Broom. It forms a semi-pendulous bush from 4 feet to 8 feet in height, and flowers freely in May.

***C. Ardoinii*.**—A dwarf species from the Maritime Alps. It rarely exceeds a foot in height, and is therefore a good shrub for the rock garden. It produces small yellow flowers in May.

***C. Beanii*.**—A dwarf hybrid raised at Kew and named after the Assistant-Curator, Mr. W. J. Bean. It is a gem of the rock garden, its golden yellow flowers being produced freely in May.

***C. biflorus*.**—This makes a neat shrub almost 5 feet high, and is one of the earliest to flower, its small yellow blossoms being produced in pairs in April.

C. Dallimorei is another hybrid raised at Kew by Mr. W. Dallimore, after whom it was named. Its parents are *C. alba* and *C. scoparius andreanus*,

and it is intermediate between the two. It forms an erect bush several feet in height, and produces its curious purplish-coloured flowers freely in May.

C. decumbens is a native of Europe, and, like *Ardoinii*, is best suited for the rock garden. It rarely exceeds 6 inches in height, and has yellow flowers which open in May.

***C. kewensis*.**—This is a beautiful little hybrid that was raised at Kew some years ago. Owing to its prostrate habit it is well adapted for the rock garden. At Friar Park Sir Frank Crisp has it planted in colonies at the summit of large boulders, so that its shoots hang partially suspended over miniature precipices. When clothed with their pale cream-coloured flowers in May, the plants give one the impression of a cascade of flowers.

***C. nigricans*.**—This is a late-flowering European species, its deep yellow blossoms opening in July. It makes shoots 4 feet or rather more in height, and flowers on the current year's wood; hence as much old growth as possible needs to be pruned away in winter or early spring.

***C. præcox*.**—One of the prettiest of the early flowering Brooms. It grows from 6 feet to 8 feet in height, and flowers when quite young. Its blossoms are creamy white, and usually open during the last week in April.

***C. purpureus*.**—This is a dwarf-growing species when pruned annually as already advised. It produces its purple flowers in May.

C. scoparius is our wild Broom, and is well known to every lover of the country. There are several beautiful varieties of it, the one named *andreanus* being most frequently met with. It has the same habit and freedom of flowering as the type, but each of the wing petals is heavily blotched with warm, brownish crimson. The Moonlight Broom, *C. scoparius sulphureus*, is another beautiful variation of the wild Broom. It has pale sulphur-coloured flowers, which are produced in great profusion in May. It has a rather more prostrate habit than the type.

The Yellow Spanish Broom.—This belongs to another family, its botanical name being *Spartium junceum*. It thrives under similar conditions to those advised for the Brooms proper, and produces seed freely, from which young plants are easily raised if the seeds are sown in pots in a cold frame. It makes a bush 8 feet or more in height, and flowers for a long time during July and August. H.

STORAGE AND DISPOSAL OF APPLES AND PEARS.

THE following special leaflet has just been issued by the Board of Agriculture: "It is believed that there is a very large number of gardens and small orchards in which Apple and Pear trees are to be found, the fruit of which is not put to its most profitable use by the owners. Much is wasted altogether, and more suffers in quality through the neglect of certain simple precautions.

Picking the Fruit.—In the first place, many varieties of Apples and Pears are picked too soon. The reasons which make it sometimes necessary for a large grower to pick his fruit before it is ripe seldom apply in the case of the small grower. Early varieties can be picked before they are fully ripe and allowed to mature in a cool room.

All late varieties, however, should be allowed to hang on the tree as long as possible. Such varieties are, among Apples, Lane's Prince Albert, Newton Wonder, Wellington, Norfolk Beefing, Claygate Pearmain, Winter Pearmain or Duck's-bill, Mannington, Sturmer, Alfriston and Court Pendu Plat; and, among Pears, Catillac, Easter Beurré, Beurré Rance, Chaumontel, Beurré Diel, Duchesse d'Angoulême and Doyenné du Comice.

Fruit of these and other late varieties should be allowed to remain on the trees till the fruit comes off easily when the Apple or Pear is lifted and given a slight twist. Care should be taken not to break off the young fruit-buds at the base of the stalk, and, of course, fruit should never be gathered by shaking the tree or other violent method. Fruit which is to be kept must be gathered into a basket, preferably lined with some soft material, such as a piece of cloth, to prevent bruising. Diseased and damaged fruit should be placed in a separate basket.

Storing the Fruit.—The requirements for the proper storage of Apples and Pears are not the same. Apples require to be kept in a cool and rather moist place, where there is enough ventilation to prevent saturation. Pears require warm, dry surroundings, but even under the most favourable conditions they will not keep long.

A few days after Apples are put in store they begin to "sweat," and continue to do so for about three weeks. During this time there must be a free current of air round them, which must not be too dry, or they will begin to shrivel. After the "sweating" period is over, this is not so important. Small growers who have only a few Apples to keep will find that a good method is to wait till "sweating" is over, and then pack them as closely as possible in a large earthenware jar. The jar should be covered with a piece of roofing slate or stone and stored in a cool shed or cellar, and the Apples will keep plump and good as long as it is possible to keep the variety. For larger growers a shed or storehouse is required if no cool cellar is available, and in preparing a store the following points should be remembered:

1. The fruit must be protected from frost, but subject to this precaution the temperature should be as low and equable as possible. A cave in a sand or chalk bank makes an excellent storehouse.

2. A moist atmosphere is necessary. The best kind of floor is the bare earth, which may be damped occasionally.

3. Ventilation to prevent stagnant and heated air is necessary, especially during the "sweating" period.

4. Apples easily absorb flavours from their surroundings. They should not be put on new wooden shelves, or on straw or hay, nor should any strong-smelling vegetable or other material be kept in the same room. They should be placed on slate shelves, or old seasoned wood may be used.

A useful Apple store may be made by digging a large trench about ten feet wide and as long as is required. The depth should be about two feet. A wall one brick thick and about four feet high should then be built on either side, and the soil that has been dug out should be heaped up against the outside of the wall. A roof of rough rafters thickly covered with thatch should be built over the top, and shelves can then be fitted inside, on

which the Apples may be heaped. There should be a door at each end so arranged as to admit air and exclude light.

Apples should never be stored in an attic or top room of a house.

Grading of Apples and Pears.—If the fruit is to be consumed by the grower, there is no advantage in selecting the fruit beyond the fact that it is better to eat the riper specimens first. If the fruit is to be sold, it is very important that all the Apples or Pears offered for sale should be of similar size and quality. The practice of "topping" the consignment with a better class of fruit cannot be too severely condemned.

The following recommendations are offered for the guidance of growers who consign their fruit to market:

1. Apples and Pears should be packed in boxes of uniform size, and should contain as far as possible the same number of fruits. It is more important, however, that the net weight of the consignment should be the same than that the number should be constant. A convenient size for the boxes is 20 inches long, 10 inches deep and 11 inches broad—all inside measurement. These boxes will hold about forty pounds. They can be obtained from box-making firms.

2. The approximate weight should be put on the outside of the box as an indication to the seller of its contents.

CYTISUS KEWENSIS, A CHARMING DWARF SHRUB FOR THE ROCK GARDEN.

3. The name of the consigner, or some mark by which the salesman can identify him, should be put on the box.

Fruit thus consigned should secure a more ready sale than fruit badly and irregularly packed, and will lead to better prices and further orders.

Small growers are strongly advised to satisfy the local demand for fruit before consigning to large markets, as the risk of a glut and consequent unremunerative prices is thereby avoided."

NOTES ON CHRYSANTHEMUMS.

AFTER many months of close attention to the welfare of the plants, the cultivator will now have a good idea of the quality of the blooms. All the plants for the production of large blooms, and others that are to be used for the furnishing of the conservatory, greenhouse and porch during the weeks of November and the early part of December, will now be under glass.

Ventilation.—The cultivator must study the state of the weather day by day. The plants need abundance of fresh air without being subjected to cold draughts, so that when the weather is favourable all ventilators should be opened wide, especially when there is a calm. As the colour of the petals shows and, in the case of the earliest varieties, as their blooms open, less air must be admitted. The fullest ventilation should be given from ten o'clock to two o'clock. Gradually increase the ventilation, and also gradually decrease it in the afternoon. A very sudden decrease would result in much moisture settling on the blooms, and if this happens day after day for a fortnight or so without adequate artificial heat to dispel it, then the blooms may become spotted and partly spoiled. Always reduce the amount of front air more than the top, and as the blooms approach full development, almost close the front ventilators.

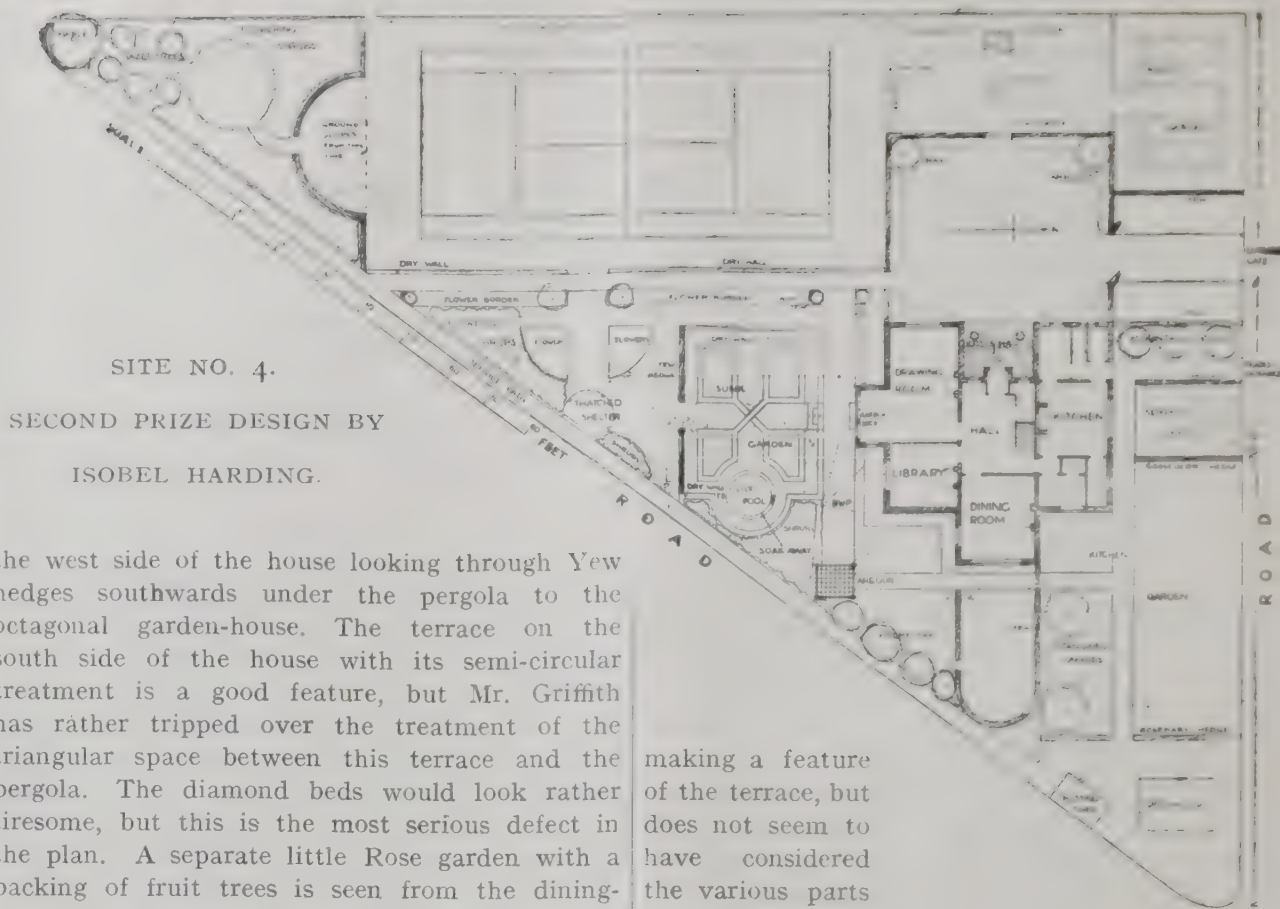

Watering and Feeding.—As the pots are closer together than they were outside, and as less air can pass them, the soil does not dry up as quickly now that the plants are sheltered. Only apply water in the forenoon, and also any liquid manures. Keep the soil in a regular state of moisture and be careful not to overfeed the plants. It is an excellent plan to mix an approved artificial manure with some rich sifted loam—loam and leaf-soil in equal proportions—and put on a very thin layer of the mixture once a week. All water supplied must be given through a rosed watering-can. Avon

THE LITTLE GARDEN.

FURTHER COMPETITION NOTES.

WE now continue our notes on some of the prize designs. Miss Isobel Harding secured the second prize for Site No. 4 with a well-thought-out scheme, which successfully avoided the difficulties of the triangular space south of the main front. From the garden door to the drawing-room there would be a pretty prospect across the sunk garden to the thatched summer-house. From the dining-room a pretty outlook is given into the little Yew-hedged garden with a semi-circular end. The standard Apple trees to the north of this little spot form a good screen between the pleasure garden and the kitchen garden, and also shut off the business corner of the garden devoted to greenhouse and potting-shed. The Mountain Ash trees between the main entrance from the road and the trades entrance would also form a satisfactory screen, and the servants' little garden is pleasantly disposed to give an outlook from the kitchen window. The entrance court is neatly managed, with a Rose garden to the north-west of it and a sundial and seat on the axial line of the entrance door of the house. The south corner is also well contrived, and the chief defect of the scheme is the provision of the long service path along the south-east boundary which borders on a road. This would give to the passer-by an unattractive impression of the whole garden, and would be uninteresting from within.

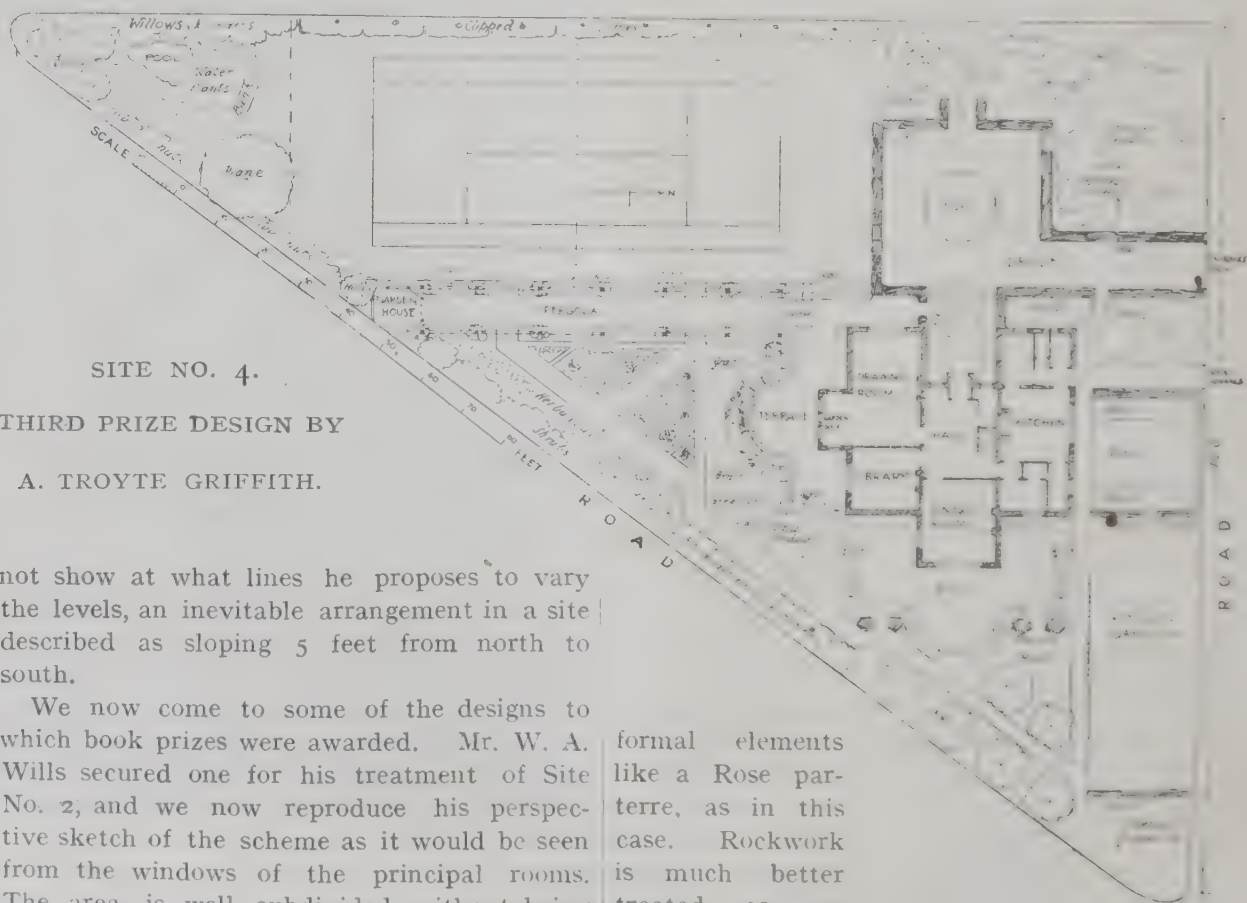

The third prize for Site No. 4 was awarded to Mr. A. Troyte Griffith. The little hedged entrance court is distinctly successful, with its trees and spring garden on the west side. The tennis lawn is placed north and south, and the south angle of the site is well employed as a little pool garden where water plants could seek hospitality. The best feature of the scheme is the very charming view which can be got from the paved space on

SITE NO. 4.
SECOND PRIZE DESIGN BY
ISOBEL HARDING.

the west side of the house looking through Yew hedges southwards under the pergola to the octagonal garden-house. The terrace on the south side of the house with its semi-circular treatment is a good feature, but Mr. Griffith has rather tripped over the treatment of the triangular space between this terrace and the pergola. The diamond beds would look rather tiresome, but this is the most serious defect in the plan. A separate little Rose garden with a backing of fruit trees is seen from the dining-room. The kitchen garden in the north-east corner would be better for some more definite screen. The servants' little garden opposite the kitchen window, with its grass plot and herb border screened from the road and trades entrance by a Laurel hedge, is happily arranged. A defect of the design is that Mr. Griffith does

making a feature of the terrace, but does not seem to have considered the various parts of the garden in relation to the garden doors of the house. He has ventured upon that very difficult problem the design of a rock garden, and, it can scarcely be said, with any great success. In a general way it is better not to attempt to combine rockwork with

SITE NO. 4.
THIRD PRIZE DESIGN BY
A. TROYTE GRIFFITH.

not show at what lines he proposes to vary the levels, an inevitable arrangement in a site described as sloping 5 feet from north to south.

We now come to some of the designs to which book prizes were awarded. Mr. W. A. Wills secured one for his treatment of Site No. 2, and we now reproduce his perspective sketch of the scheme as it would be seen from the windows of the principal rooms. The area is well subdivided without being too much cut up, and the curved edge at the end of the lawn, with its Yew arch leading to a pergola, would make an effective little scheme, the vista being closed by an octagonal arbour. The kitchen garden is divided in a practical way, and it is evidently the intention to divide it from the flower garden by a stout hedge, though this is not shown on Mr. Wills' plan.

We also reproduce Mr. Weall's design for Site No. 2, which also secured a book prize. He has utilised the slope of the site by

formal elements like a Rose parterre, as in this case. Rockwork is much better treated as an independent item, and altogether screened from the more regular features of the garden. The placing of the Rose pergola has also proved somewhat of a snare. It has its value in dividing the Rose garden from the herbaceous garden, but it is placed over a path which does not lead to anywhere in particular. The pergola should always be regarded as a connecting link between two definite parts of the garden, and not as a thing which is justified in its own right wherever it may be put.

SITE NO. 3.—THIRD PRIZE DESIGN BY
KENNETH DALGLIESH.

Miss Norah Geddes has devised an interesting and simple scheme for the same site, but, as in all the designs she submitted, has concentrated too much attention on flowers, to the almost complete disregard of vegetables. The scheme, therefore, is not so well balanced as it should be. In a design of this kind, which is very simple in its outlines, success would depend chiefly on the planting scheme. The little arbour seat to the north of the lawn is intended to be covered with Sweet Pea Tennant Spencer, Clarkia, Delphinium, Monthly Roses, &c. The same criticisms apply to the design by Miss Geddes for Site No. 3 (not reproduced). The scheme is good, but there is no space allowed for vegetables,

SITE NO. 2.

DESIGN BY

W. A. WILLS.

which is hardly reasonable in a garden of such a size.

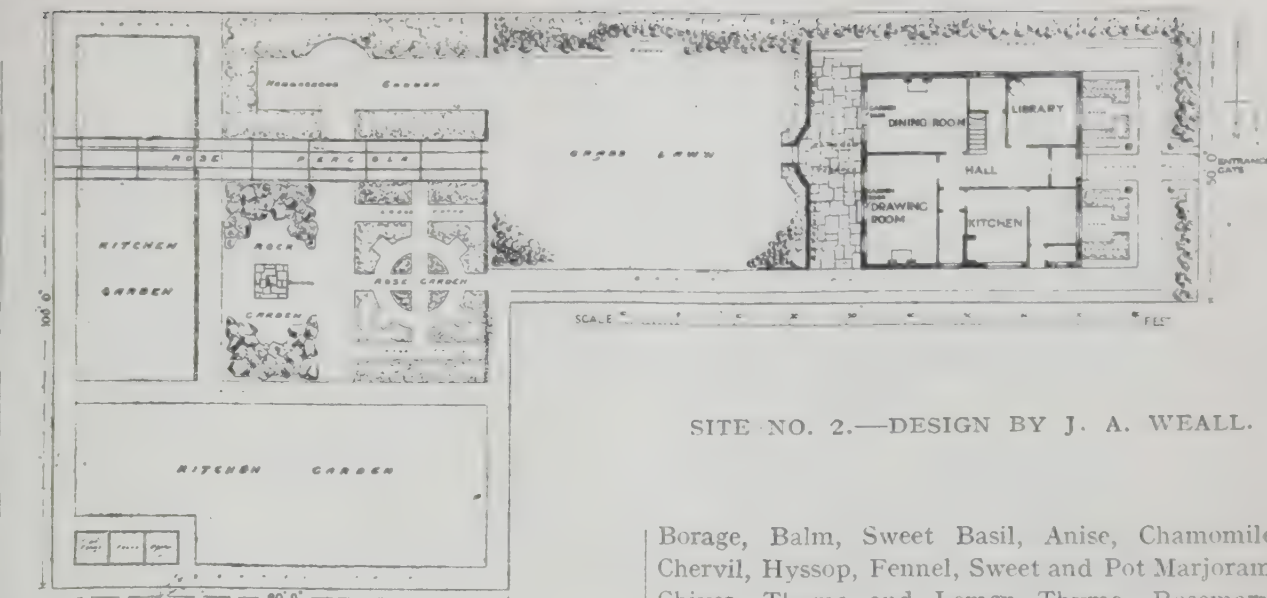

A final series of prize designs will be reproduced next week.

L. W.

SEASONABLE NOTES ON VEGETABLES.

Cabbages.—Continue to put out batches of plants on vacant plots, where Potatoes have been lifted, for example. All that is required in the way of preparation is to remove the haulm and any diseased tubers, and level the surface with a fork or rake. Draw drills 18 inches or 2 feet apart with the corner of a hoe, and dibble the plants in 9 inches apart if space is limited, as alternate plants can be cut out in the spring when half-grown to give space to those left to grow to full size. Give the plants a good soaking of water to induce them to make a quick start into growth. Such varieties as Favourite, April, Harbinger, Pioneer, Model and Springtide are all good.

Celery.—Continue to earth up all batches as growth proceeds. In the case of that blanched with brown paper for early supplies, and also the latest batch which has not been earthed

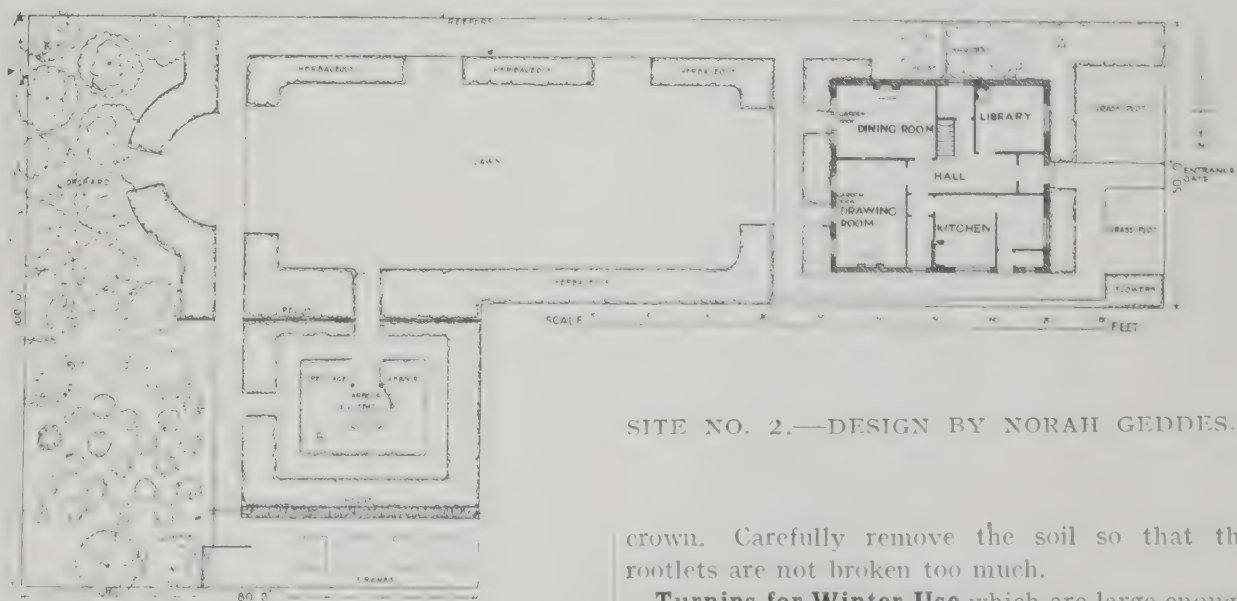

SITE NO. 2.—DESIGN BY J. A. WEALL.

at all, give the roots a thorough soaking of water before earthing, which will hasten growth considerably. When earthing Celery with soil, great care should be taken to make sure the soil does not get into the centre of the plants or be chopped down from the side in large lumps, which press unduly on the plants, forcing them out of an upright position, and rendering them unsightly when dug. In chopping the soil down on each side of the trench, it should be made quite fine and be evenly placed about the plants, at the same time holding these quite upright with the leaves kept close together, either by tying them with raffia or held

Borage, Balm, Sweet Basil, Anise, Chamomile, Chervil, Hyssop, Fennel, Sweet and Pot Marjoram, Chives, Thyme and Lemon Thyme, Rosemary, Horehound, Parsley, Winter Savory, Dill, Rue and French Sorrel. Quite small pieces of each quickly grow into serviceable clumps. After planting, mulch the surface with half-decayed leaves mixed with old potting soil and wood-ashes.

Rhubarb.—Lift crowns for an early supply, placing them in a Mushroom-house where such a structure exists. Under the stage in the greenhouse or stove, or in a closely fitting deep box in the stokehole near the boiler will suffice if sufficient moisture is provided.

Salsify and Scorzonera should be lifted and stored in road sand in a cool frost-proof shed or cellar, cutting off the tops not too near the

SITE NO. 2.—DESIGN BY NORAH GEDDES.

crown. Carefully remove the soil so that the rootlets are not broken too much.

Turnips for Winter Use which are large enough should be stored in a cool place in sand, first cutting off their tops not too close to the crown. A little frost would not hurt them, but the storing checks the growth. Later crops which are half or less grown should have the soil frequently stirred between the rows, and, if a tender variety, should, on the approach of frost, have a little soil drawn over the crowns as a protection.

Parsley.—Thin the plants where too crowded, either by removal of the large old leaves or by drawing a plant here and there, as, the stockier the plants are, the more likelihood there will be of their standing well through the winter. Continue to prick out plants in frames as a certain means of providing a full supply during adverse weather in the winter. Temporary turf pits covered with old lights answer this purpose. Any means adopted of affording protection from snow, frost or heavy rain is all in favour of this herb.

Carrots.—The main batch should be lifted, cleaned, dried and stored in sand in a frost-proof

by the hand while the soil is placed around the plants.

Herbs.—Now is a good time to replant, reduce or increase the varieties, according to requirements. As a rule, these necessary ingredients of the kitchen are almost ignored or put in any out-of-the-way corner and much neglected. A narrow east border is a suitable site. Each kind should have its small allotted space, and, when carefully attended to, this phase of the garden can be made quite interesting and useful. Deeply trenched but not too heavily manured soil is necessary to ensure success. If the soil is stiff and retentive of moisture and naturally cold in the spring, deep trenching is a boon to these plants, as they lie drier during the winter and are not nearly so liable to decay at the roots. Small patches of each will be ample to meet the requirements of an ordinary household. The salient kinds are Mint, red and green Sage, Tarragon,

shed. Growing plants in frames should be thinned, the soil stirred, sprinkling soot over the leaves, and keeping the frames closer and protected at night to encourage quick growth.

Seakale.—An early batch of roots should be dug up and placed in their winter quarters, whether in large pots with an inverted one on top, or in boxes or pits in the Mushroom-house, and be kept

next is 6 inches to 7 inches from the first, and so on for four or five rows, increasing the next few rows to half an inch wider apart. The first circle is then drawn with a peg round the centre, and the first row of Aubrietias planted 7 inches to 8 inches apart. To ensure the Tulips coming alternately in the row, the Aubrietias in the rows must be even in number. Thus, if eight

moist and free from light by covering the crowns with freshly gathered clean Oak or Beech leaves.

Swanmore, Hants.

E. MOLYNEUX.

SOME HINTS ON SPRING BEDDING.

(Continued from page 503.)

HAVING given a brief account of how the plants are produced, I will now describe how the beds are planted. For a number of years I have adopted a system of planting the principal beds with early and May flowering Tulips in the same bed, selecting as nearly as possible the same colour from each class, thus prolonging the show of bloom to two months instead of one, the May-flowering Tulips coming into flower as the early ones go off. As the season of growth is limited, thick planting is necessary if the beds are to be effective; also the bulbs are planted in between the plants in the row, and not between the rows, thus giving room for the use of the Dutch hoe in the early spring without any fear of injuring the bulbs.

The beds in the principal gardens here are circular and oblong alternately on each side of the main path or thoroughfare to the sea. They are usually planted in pairs opposite each other. The circular beds are 14 feet in diameter, and have one tall *Dracæna australis* in the centre of each. The oblong beds have semi-circular ends, and are 23 feet by 14 feet.

Preparing the Beds.—The beds are prepared in the usual way, dug deeply, and manured where necessary. Soot is added where Pansies and Violas are planted, and lime in the Wallflower beds. If possible, the beds are dug over in the morning of the day they are planted, well trodden with the feet, and raked over with a wooden rake. By so doing they are in much better condition for planting than if dug a few days previously. The circular beds are marked out as shown in Fig. 1 for convenience in planting. Assuming the bed is for Aubrietia, with two rows on the edge for white Daisies or *Alyssum saxatile compactum*, the first peg is 8 inches from the grass edge, the

plants are in the first row, eight Tulips can be planted, four of each, early and May flowering.

Planting.—The Aubrietias are first planted firmly and then the bulbs between them, each row being completed before another is begun. This is continued right out to the third row from the edge. The two rows of edging are planted without any bulbs between them. The foregoing remarks also apply to all the circular beds planted with Pansies, Violas, Polyanthuses, double Arabis, Daisies and Myosotis. The circular beds of Wallflowers are planted in a similar manner; but the space between the rows and the plants in the row is increased according to the size of the plants, viz., 8 inches to 9 inches between the rows and 10 inches to 12 inches between the plants. In the latter are usually planted old May-flowering Tulips or tall-growing Narcissi between the plants.

The Oblong Beds are planted in the same way as the circular ones, the rows marked at the end with

FIG. 2.—(1) 24 FEET \times 9 FEET; (2 AND 3) 34 FEET \times 4 FEET 6 INCHES; (4 AND 5) 18 FEET 6 INCHES \times 4 FEET 6 INCHES; (6 AND 7) 33 FEET \times 4 FEET 6 INCHES.

pegs as shown in Fig. 1. Planting is begun in the centre and planted zigzag as shown. In planting the bulbs in the last row each side, they are continued round the ends between the plants.

Some Excellent Arrangements.—The following are some of the arrangements of plants and bulbs in the oblong and circular beds, as shown in Fig. 1:

1. Aubrietia Hendersonii, two rows of white

Daisies, early Tulip Ophir d'Or and May-flowering Tulip Bouton d'Or.

2. Aubrietia Model, two rows of *Alyssum saxatile compactum*, early Tulip Princess Marianne, and May-flowering Tulip Picotee. Other Tulips which may be used are Yellow Prince (early) and *gesneriana lutea* (May-flowering).

3. Double Arabis, two rows of Aubrietia Model or Dr. Mules, early Tulip Thomas Moore and May-flowering Tulip La Merveille. Other Tulips: Dusart, Mr. Stanley or Prince of Austria (early), and *macrospeila*, *gesneriana rosea* and *g. major* (May-flowering).

4. Polyanthuses (yellow or white), two rows of crimson Polyanthuses or two rows of pink Daisies, early Tulip President Lincoln and May-flowering Tulip Blushing Bride. Other Tulips: Eleanor (early) and Inglescombe Pink (May-flowering).

5. Pansies or Violas mixed (two rows of white or two rows of yellow), early Tulip Keizerskroon and May-flowering Tulip Royal Crown.

6. Giant White Daisies and two rows of Aubrietia Dr. Mules. Tulips as in No. 3.

7. Myosotis Royal Blue, two rows of *Alyssum saxatile compactum* or two rows of Giant White Daisy. Tulips as in Nos. 1 and 2.

8. Wallflowers (dark) and two rows of yellow, cream or white *Narcissus Poeticus ornatus* or *N. Poetaz Elvira*.

9. Wallflowers (yellow, cream or white), two rows of dark Wallflowers or two rows of Myosotis Royal Blue and Tulip *gesneriana rosea* or *g. major*.

The foregoing, I think, gives a fair idea of how the beds may be planted. In Fig. 2 I give particulars of a portion of the beds in another garden and a description of how they were planted one season.

1. Wallflowers (dark), two rows of double Arabis and *Narcissus Poeticus ornatus*.

2 and 3. Polyanthuses (mixed), one row of yellow Polyanthuses, early Tulip Artus and May-flowering Tulip Blushing Bride.

4 and 5. Polyanthuses (crimson), one row of white Polyanthuses, early Tulip Ophir d'Or and May-flowering Tulip Bouton d'Or.

6 and 7. *Erysimum Golden Gem*, one row of Aubrietia Model, early Tulip Mr. Stanley and

May-flowering Tulip Inglescombe Pink. The *Erysimum* is a good spring bedding plant, flowering earlier than the Wallflower, and I grow it the same as described for the Wallflowers.

I could give many other ideas for planting beds and borders, but the foregoing I consider sufficient to guide anyone interested in the subject.

J. B. STEVENSON.

Chine Cottage, Bournemouth.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

The Early Vinery.—If ripe Grapes are required in May, this should be shut up during the first week of November and started with a night temperature of 55°. Maintain a moist atmosphere by frequently syringing the walls and floor of the house, and the Vines will benefit by a light damping when the weather is bright. When the buds begin to swell, the night temperature must be raised to 60°. The border should be examined and, if dry, thoroughly moistened with clear soft water at a temperature of 70°.

Early Figs in Pots.—These should be placed under cover at once. Examine the crocks of each pot, and give a surface-dressing of loam and decayed manure. This must be made firm, leaving sufficient space for a liberal supply of water.

Strawberry Plants for Forcing.—Careful attention will be necessary with regard to watering these plants. If dry weather continues, the roots must not be allowed to suffer for the want of water. On the other hand, if heavy rain sets in, the plants will require the protection of a cold frame, especially those plants for early forcing.

Plants Under Glass.

Roses in Pots which have been grown in the open during the summer should now be removed to some sheltered position where the pots can be protected from frost in the winter. If a few early blooms are desired, a limited number of plants may be placed in gentle heat now, but previous to this the drainage should be examined and the pots washed, after which a top-dressing of rich loam and decayed cow-manure may be given.

Violets in Pits.—Abundance of air should be given to Violet plants in pits; in fact, they will benefit by the removal of the lights during mild weather. If the soil is at all dry, a thorough watering ought to be given before it is necessary to close the pits at night. Nothing is more detrimental to Violets during the winter than a close, stagnant atmosphere.

Achimenes and Caladiums.—The pots containing these tubers should now be laid on their sides under the stage of a warm house, where they may remain during the winter.

Palms.—Now that the pots are well filled with roots, an occasional watering of liquid manure may be given. Take advantage of dull days to sponge the foliage, and if scale or other insects are present, some approved insecticide should be employed to destroy them. Syringe the plants freely during bright weather. Very little shading or airing will be necessary now, providing the atmosphere is kept sufficiently moist.

The Flower Garden.

Spanish Irises and late-flowering Tulips should be planted at once if not already done. The soil for this purpose must be rich and deeply cultivated if the best results are to be obtained. Old clumps of these bulbs should be lifted before growth commences, and the soil enriched by a good dressing of old manure from the Mushroom-house or a spent hot-bed. Deep cultivation is of more importance than many people think.

Violas.—If the old plants have been cut back in the autumn, numerous young shoots should now be ready for propagation. If carefully removed from the old stools and inserted in sandy soil quite near the glass in a cold frame, they will soon make roots. Keep the pit closed until growth commences, after which the lights must be removed until sharp frost sets in. By this means good, strong plants will be ready to put out in March.

Antirrhinums.—Cuttings of the best varieties may still be taken and inserted in pans or boxes with a view to retaining distinct colours for early summer blooming. In selecting the cuttings, only such as are without flower-buds ought to be taken. The soil should be freely mixed with sharp silver sand.

The Rock Garden.

Plumbago Larpentæ.—This is a very desirable plant for the rock garden. In September it is covered with beautiful blue flowers, and lasts so until the end of October, or later if the weather is mild. In all cases it is desirable to plant in a sunny position, either above the upper edges of vertical stones on the rockwork or on a sunny bank. Sandy loam is the most suitable soil for it. The stock may be increased by division either after flowering or in the spring.

Hardy Fruit.

The Fruit-Room.—There must be no lack of attention in the fruit-room for the next two months. Give just sufficient air to carry off the moisture, but nothing more at present, for a strong current of air is almost sure to cause early fruits to shrivel. Examine the fruits twice weekly, and remove all which show signs of decay.

Wall Trees.—While the weather is favourable the planting of wall trees should be pushed forward as quickly as possible. See that the soil is thoroughly drained and of such a nature as will promote the growth of clean, healthy trees. If young, home-grown trees are available, they may be lifted and transplanted with a good ball of soil, with a fair prospect of carrying a few fruits next season. In the case of Apricots and Cherries, a good quantity of old lime rubble ought to be mixed with the soil, especially if this is of a heavy nature.

The Kitchen Garden.

Leeks.—The main crop of Leeks should be given frequent waterings of liquid manure. Few garden crops will repay the cultivator better for liberal treatment in this way than the Leek, which is a gross feeder, and the larger the specimen the better will be the flavour.

Winter Spinach.—All decaying leaves must be removed as they appear and the soil between the rows moved with a Dutch hoe. A slight sprinkling of soot should be applied to promote healthy growth and keep slugs in check.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Parsley.—To provide a constant supply of this indispensable garnishing during the winter requires somewhat more than ordinary attention bestowed on its cultivation. As has already been pointed out, the plants for this supply should now be safely under the protection of at least a cold frame. To give a constant supply it will be necessary to pick the Parsley fairly close and remove all decayed leaves from time to time. Where, however, a very limited supply is required, a few plants should be carefully lifted, potted into 6-inch pots, and placed in a cold frame or on a greenhouse shelf, where a useful picking may be had.

Cabbages.—To provide a supply to follow those that were planted towards the end of August, a few plants may still be planted in rows on ground that has recently been cleared of late Potatoes.

Herbs.—Although a number of these will have been cut and dried for winter use, they are poor substitutes for the fresh young leaves that can be obtained from plants that are forced. As Tarragon and Mint are the two most in demand, a few roots should be lifted, placed in boxes, and introduced into heat as required. In this connection it is important to remember that as they are moisture-loving plants, they must on no account be allowed to become dry at any time.

The Flower Garden.

Violas.—In many districts difficulty has been experienced in securing a sufficient number of cuttings of some of the best varieties. There need not, however, be any alarm in this respect, as with a good, healthy stock there is still time to make up the shortage. If each cutting taken now has a small portion of the root attached, it will quickly establish itself in a cold frame. Old roots should be run out into nursery lines,

and, if required, can be divided and planted in the spring.

Montbretias.—In many cases it is not necessary to lift and store Montbretia bulbs in the late autumn. Still, in the majority of places in the North it will be advisable to lift and store the bulbs as soon as the foliage dies down. Place them in boxes of sand and store in cold frames. During wet weather, or when outside work is at a standstill, the clumps should be divided, selecting the largest bulbs and replacing them again in boxes until planting-time in the spring. In the case of choice varieties, the small bulbs ought to be preserved and planted out in the reserve border, where by another season they should attain flowering size.

Plants Under Glass.

Freesias.—The earliest lot should now be sufficiently advanced to admit of the plants being gently forced; this must, of course, be done gradually. The shoots should be neatly staked and the plants kept as close to the glass as possible. As soon as the flower-buds appear, liquid manure may be given, or, failing that, some approved plant food.

Cyclamen.—Young plants from a sowing made in August should now be ready for pricking off. Prick these into shallow boxes about three inches apart, using a compost comprising loam, leaf-mould and good silver sand. The moving of the tiny plants must be carefully done, as the roots are easily damaged. These may, of course, be placed in small pots at once, but when boxes are used the plants seem to get away better. Place them near the glass in a temperature of about 60° and syringe lightly on fine days.

Richardias (Arums).—In order to have these in flower by Christmas, no time must be lost in putting a number of plants into heat. For this early flowering select plants that have not been turned out of their pots during the resting period, as it has been found that they force more readily than those that were planted out. As soon as growth advances they should be assisted with liquid manure or some good fertiliser.

Cinerarias.—After this date it will not be safe to let these remain in cold frames, unless, of course, they can be heated in some way. In any case perhaps it will be better to stand them in a cool, airy house where fire-heat is only turned on to exclude frost. In turning them over, make a close examination for leaf-grub and have it destroyed. The house must be fumigated at intervals to prevent an attack of green fly.

The Hardy Fruit Garden.

Gooseberry and Currant Cuttings.—Although young bushes of these can be bought for a very modest sum, it is sometimes advisable to have a stock of home-raised bushes. In the case of Gooseberries and Red and White Currants, the cuttings should be selected from straight, medium-sized growths, with a heel attached if possible; this, of course, is not necessary. Rub out the lower buds to prevent suckers appearing. These cuttings ought to be shortened somewhat and placed upright in a trench 6 inches deep, and when filling in the soil see that the ground is made very firm. In the case of Black Currants, the same treatment should be given, except that the buds must not be removed from the lower part of the shoot. With Black Currants suckers are to be encouraged.

Fruit Under Glass.

Figs.—Unless the roots of Fig trees are confined in a comparatively small space by means of brick walls, it is very difficult to keep them in a fruitful state. Trees that have made an abundance of growth usually produce a very poor crop of fruit. These should now be attended to, and in some cases drastic measures must be resorted to. Open a trench round the tree and as close to the trunk as can be done with safety. Fork out the soil from underneath, cutting back all strong roots going downwards and trimming any that may be damaged. Before proceeding to fill in the trench, ram some lime rubble or broken bricks underneath the ball to encourage surface rooting. In filling in the trench, use good loam and lime rubble, and on no account add manure to the soil.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Lælia pumila alba Orchid Dene Variety.—The pretty and pure white dwarf-growing variety bore a one-flowered scape perhaps not more than 4 inches to 5 inches high. The flower, however, was exceedingly pure in tone throughout, and very solid-looking. From Messrs. E. H. Davidson and Co., Twyford.

AWARDS OF MERIT.

Lælio-Cattleya Lady Oliphant (L.-C. Norba × Souv. de Queen Victoria).—A distinct and beautiful variety in which the sepals and petals are soft chrome yellow, the pronounced fringed lip being wholly coloured rosy crimson. From Pantia Ralli, Esq., Ashtead Park.

Carnation Wivelsfield White.—

This handsome variety has been exhibited on many occasions, though not hitherto presented for an award, the raisers preferring to first fully test its merits. It now figures among the indispensable market whites—no mean tribute to the excellence of a Carnation of any colour to-day. Wedded to purity of tone, informality and easy development is a fragrance that will render it popular in any collection. From Messrs. Allwood Brothers, Hayward's Heath.

Begonia Mrs. Harry Barton

(see illustration).—In specimen form, as shown, this is decorative and distinct in colour, the creamy-coloured flowers, profusely borne, extending in well-branched trusses. So far as we remember, nothing like it in the winter-flowering Begonias has appeared hitherto. It is said to be a sport from Emily Clibran. Exhibited by Miss Tanner, Caldecote Towers, Bushey Park, Herts.

Chrysanthemum James Stredwick.—

An exhibition Japanese variety of goodly proportions with drooping florets, and coloured a terra-cotta shade. The variety as shown displayed not a little refinement. From Messrs. J. Stredwick and Sons, St. Leonards-on-Sea.

Chrysanthemum W. Rigby.—

An exhibition Japanese variety of the incurved type. It is of massive proportions, without coarseness, and of a rich yellow colour. Handsome from the exhibitor's standpoint. Exhibited by the Rev. Canon Cooper Marsden, D.D., Bickley, Kent.

Dahlia Deveron.—A Collarette variety of rosy cerise tone and nearly white inner florets. It is exceedingly showy, and of a shade that shows well under artificial light. From Messrs. Dobbie and Co., Edinburgh.

NEW FRUIT.

Apple Harry Pring.—A culinary sort which received an award of merit when shown as

gathered fruits in February last, subject to it passing the cooking and cropping tests, and also that of habit of growth. These having proved satisfactory, the award has now been confirmed. No fruits were shown at this meeting. Exhibitor, Mr. Peters, Leatherhead.

All the foregoing were shown before the Royal Horticultural Society on the 20th inst., when the awards were made.

BOOKS.

Recent Investigations on Apple Scab.—

A large amount of literature has appeared dealing

browned. On the fruit almost black spots, becoming reddish brown and sharply bordered, are produced, the central part finally becoming brown, bare and corky, with a black margin. Cracking of the fruit occurs in many varieties. The disease also attacks the twigs, apparently rarely in America, more commonly in this country. McAlpine estimated the loss due to this disease in Victoria to amount to £40,000, and the author estimates the loss in the States, where there are over five million acres of Apples, at approximately nine million pounds sterling. Not only is the market value of the Apples diminished by the attack, but they are rendered smaller, and various rot-producing fungi attack them through the damaged spots. All the species of *Pyrus* of the

Apple group appear to be open to attack, including *Pyrus spectabilis*, *P. Kaido*, *P. floribunda*, *P. baccata*, *P. prunifolia*, *P. rivularis* and *P. dioica*, and the fungus can apparently pass from one species to another. The similar disease on the Pear is, however, produced by a different species of fungus, though very closely allied. The author gives a long and valuable account of the various stages through which the fungus pass, which we may pass over, and turn to the measures of control which he advocates. These consist of (1) sanitary measures, (2) selection of resistant varieties, and (3) spraying. The sanitary measures include the turning in of dead leaves and the pruning of the tree so as to keep it open. In addition, in England the cutting out of infected and dying shoots is important. Unfortunately, few varieties really worth growing are free from scab attack, so that selection of resistant varieties offers little hope of success in Apple-growing. Along with sanitary measures, spraying is important. Dust sprays can be employed with greater economy than liquid sprays; but, unfortunately, they do not appear to be effective in controlling the disease. Bordeaux mixture and lime-sulphur sprays seem the best, and considerable success has followed the addition of iron sulphate to the self-boiled lime-sulphur washes. The greatest importance attaches to the time of application. In the author's experience winter spraying has little effect, and he considers the best time for the first application of the spray to be just as the buds show pink. A second should be made as soon as the petals have fallen, and a third about a fortnight or three weeks after this. Sometimes another in July or August is called for. Rainy weather is the time when infection is most likely to occur, and a spray with more or less adhesive properties should be chosen so as to withstand some amount of washing without damage. These measures combined have proved very effective in the States in holding the disease in check.

THE NEW WINTER-FLOWERING BEGONIA MRS. HARRY BARTON
THE FLOWERS ARE CREAM COLOURED.

with Apple scab in all countries where the Apple crop is an important one, for, in all, scab ranks, just as it does here, as one of the worst troubles from which plants suffer. One of the latest contributions* to the subject is that of Mr. E. Wallace of the Cornell University, and it may not be inappropriate to summarise his remarks at this season, when scab is most evident. The symptoms of scab on the leaves are first an olive discoloration on the lower surface, which becomes darker and assumes a velvety appearance. On the upper surface the spots are at first lighter; later the tissue under the spot is often killed and

* Cornell Exp. Station, Ithaca, U.S.A., Bull. 335; September, 1913.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

ANTIRRHINUMS DISEASED (Oak-leaf, British Columbia).—The Antirrhinums are attacked by the fungus *Puccinia antirrhine*. This fungus is unknown on this side of the Atlantic; but, judging from the reports that have appeared and from the specimen you send us, we think it must be a very virulent disease indeed. You have done quite right to destroy the affected plants, and as the disease is unknown here, we think it extremely probable that it has been contracted from wild plants growing in its neighbourhood. Not only are Antirrhinums attacked, but some species of *Linaria* too. As a precautionary measure we advise you to spray young plants with Bordeaux mixture or with potassium permanganate at intervals all through their growth. We think if you adopt this precaution you will avoid the attack another season.

ROSE GARDEN.

SELECTION OF RAMBLER ROSES FOR SEVEN-FOOT SCREEN (M. M. K. C.).—Your selection is, on the whole, a good one; but instead of Mme. Alfred Carrière, which grows so very rampantly, and is really more suitable for a lofty arch or wall, we would suggest *White Tausendschön* or *Lady Waterlow*; and as you have no good red, we recommend *Excelsa* in place of *Climbing Captain Christy*. The variety *Juliet* is not a bedding Rose, as it flowers sparsely in the autumn. It is best grown as a pillar or free bush, when it is very beautiful.

ROSE GROWTH FOR EXAMINATION (R. F. C.).—The piece of growth sent is that of the *De la Grifferaie* stock. This stock is used by some growers for Tea and Hybrid Tea Roses. It is a very good one in many respects, but its suckers are very troublesome, and not readily detected. It is also a bad stock for mildew. Often one may see this Rose flourishing upon a wall where some climbing variety has been planted. The original Rose has died, and this vigorous stock has taken its place, to the disgust of its owner. We remember reading in one of Dean Hole's books how some enthusiastic amateur took him to view a very vigorous plant of *Maréchal Niel*, but which had never blossomed. When the witty Dean saw the plant, he could understand the reason for its not flowering, because it was simply the *Manetti* stock, which rarely blossoms. If Roses are obtained on the *Briar* stock, their suckers are readily distinguished.

FRUIT GARDEN.

BEURRE DIEL PEARS CRACKING (M. F. A.).—Please see reply to "Down Place" in last week's issue.

FIG TREE DROPPING ITS FRUIT (Mrs. Craig).—The Fig tree has failed to develop and carry its fruit to maturity because the flowers of the fruit failed to set seeds. By cutting a fruit you will see that there are no live or hard seeds in it (this is a first essential to fertility in all fruits). The cause of this is generally attributed to the soft and immature condition of the wood of the previous year's growth (the shoot which produces the fruit). The

way to remedy this is by thinning out many of the branches of the previous year's growth at the winter pruning, especially the weak shoots and in parts where the tree may be overcrowded with them. This will expose the shoots left to more sunshine and air, causing the growth of the shoots of next year to be harder, better matured and more fertile. Your tree being raised from a sucker makes no difference.

KITCHEN GARDEN.

CELERY FOR INSPECTION (Colsoncott).—Your Celery is attacked by the fungus *Septoria Petroselinii* Apii, causing disease and death of the leaves and giving them the rusty appearance they exhibit. No cure is possible when the disease has assumed the proportions it has in this case, and the best that can be done is to pick off all the diseased parts and burn them, spraying the rest with Bordeaux mixture or with potassium sulphide (1oz. to three gallons of water). The disease is carried mostly in the seed, and next year care should be taken to procure seed from a good source.

POTATO ATTACKED BY BLACK SCAB DISEASE (B. H.).—We regret to say that the Potato you send is attacked by the disease called black scab, due to the fungus *Synchytrium endobioticum*. No cure is known, and when once the disease has attacked the plants the soil is almost certain to have become affected, and succeeding crops of Potatoes are liable to the same disease. You must notify the Board of Agriculture, 8, Whitehall Place, London, S.W., of the attack. A penalty is attached to concealment or failure to give the notification. It would be well to destroy by fire all the affected tubers, and either not to grow Potatoes in the affected land for eight years at least, or to grow only varieties not subject to attack, a list of which can be obtained from the Board of Agriculture.

MUSHROOMS IN FIELD OR GARDEN (Mushrooms).—Mushrooms planted in field or garden are always an uncertain crop, and one which can never be depended on to come true to time. One season there may be a heavy crop, whereas the next year there may be none at all. Your best way to secure a succession of supplies will be to plant with spawn the area you mention, both in field and garden. It is too late to plant the spawn in the natural ground out of doors now. The best time is the end of May. Break a brick of spawn into four pieces and plant each in the ground a foot apart, always just deep enough for the pieces of spawn to be covered over an inch deep. Cover over with loamy soil and tread down very firmly. In about a month after spawning, should the ground be dry and the weather warm (not otherwise), give the spawn a moderate watering, and look out for Mushrooms at the usual time in the autumn.

HOW TO USE CHICORY (Thames Valley).—Chicory is largely grown as a winter salad, for which purpose, mixed with Lettuce and other salad plants, it is excellent. At the end of October the roots may be dug up and stored out of doors in clumps with Potatoes, or, if preferred, they may be left in the ground through the winter (the plant is quite hardy) and the roots taken up in batches for forcing as required. The forcing of the roots usually commences at the end of October, and may be continued by planting successional batches throughout the winter (provided plenty of roots are available). Cut off all the lower half of the roots and plant the top parts close together in large pots or boxes of any sort of light soil, and place in some position which can be kept warm and dark, such as a Mushroom-house or underneath the stage of a glass house or a stove house (this could be darkened). In such a position the roots would soon be excited into leaf growth. (It is these leaves so forced which are used for salad.) They should be cut off when 6 inches long before they get too old, or they become bitter and flabby. The roots are of no further use after the leaves have been cut off. They should be thrown away and the soil replanted with new roots.

MISCELLANEOUS.

WIREWORMS EATING PLANTS (C. P. L.).—Your best plan will be to trap the wireworms as completely as possible by means of pieces of Potato or Carrot sunk in the ground. Constant hoeing and cultivation throughout the season is the best means of dealing with the pest, and the use of superphosphate has some effect in keeping it in check, or causing it to keep on the move.

VARIOUS QUESTIONS (A. Vaughan).—(1) The Celery is attacked by the fungus *Septoria Petroselinii* Apii. Please refer to reply to "Colsoncott." (2) The Beet is attacked by Beet rust, due to *Uromyces betæ*. It is not likely to make much difference at this season of the year, but it indicates the lack of potash in the soil, and we advise you to give a dressing of a potassium manure, such as potassium sulphate, before growing Beet in the soil again. (3) We can find no disease due to fungus or insect attack on the foliage of the Salsify sent.

MAKING A SHELTER (W. H. B.).—Seeing that the proposed site is sheltered on all but its north aspect, it would be quite easy to convert it into a shelter, though we fail to see what service it would be for such things as Dahlias, unless these were planted within it in spring. The laths you speak of would do well for the sides, and need not be closely fixed; an inch asunder would be better. This material would be rather heavy for the top, and tiffany, scrim or canvas would do quite well, as these keep out several degrees of frost. If you make the top span-roofed, after the manner of a small greenhouse, you might use Rush or Reed mats for the top, or the ordinary Russian or Archangel mats, either of which could be fixed at the ridge and be rolled up and down at will by the aid of a pulley, cord and roller. In all the circumstances,

however, we think the sides made of laths, and with canvas or tiffany for the roof, would meet your requirements and not obstruct too much light.

VARIOUS QUESTIONS (Bourne).—With the further particulars regarding your Pelargoniums, we still think that the gas is a very likely cause of the trouble. Besides this, there are undoubtedly errors in cultivation, for you speak of giving them a little water every day. As pointed out in our letter, this is the worst possible thing you could do, the correct course being to allow the soil to become dry (not parched), and then give a thorough watering, which is best accomplished by soaking in a pail of water and allowing them to drain before returning them to their place. In all probability the roots are in a sorry plight, and this would be considerably aggravated by the frequent doses of fertiliser, as stimulants should only be used on plants whose roots are in a good, healthy state, and able to derive nourishment therefrom. If you examine the roots of your plants you will very likely find them considerably decayed, in which case the best thing to do is to shake them clear of the old soil and repot in some good, sweet compost, such as loam lightened by a little leaf-mould and sand. Until the roots are active, watering must be very carefully carried out. Gas would not in any way injure plants in the open borders near the windows of the rooms where it is used, as, of course, the fumes are at once carried away by the outside air. There are no flowering plants that would not be affected by gas in the room in which they are growing, and we can only assume that, in the case of the windows full of beautiful flowering plants of which you have been told, they were grown elsewhere and taken indoors when at their best. The most successful gas-resisting foliage plants would include *Aspidistra*, *Aralia Sieboldii*, *Araucaria excelsa*, *Asparagus Sprengeri*, *Cyperus alternifolius*, *Cordyline australis*, and the hardier Palms such as *Corypha australis*, *Lantana borbonica* and the *Kentias*, providing they have been well exposed to light and air beforehand.

NAME OF PLANT.—W. Wright.—A common tropical and subtropical annual: *Setaria glauca*.

NAMES OF FRUIT.—Mrs. Wainwright.—1, *Beurré Superfin*; 2, *Josephine de Malines*; 3, *Easter Beurré*.—J. P.—1 and 3, *Marie Louise*; 2, *Beurré Dumont*; 4, *Comte de Lamy*; 5, *General Todleben*; 6, *Maréchal de la Cour*; 7, *Beurré Superfin*; 8, *Beurré Diel*.—Subscriber.—Bramley's Seedling (big one); Cox's Pomona (middle one); deformed fruit (small one).—W. OBITUARY.

CHARLES BECKETT.

WE regret to record the death of this noted gardener, which occurred at The Rosary, Boreham Wood, Elstree, on the 17th inst. The deceased, who was in his eighty-ninth year, was for twenty-five years gardener at Remenham Lodge, Henley-on-Thames, and at that time was a very successful exhibitor at the local shows. Subsequently, and for about a similar period, he was bailiff to the late, and also to the present, Sir Philip F. Rose, Bart., at Rayners, Penn, Bucks, a position from which he retired about eleven years ago. For the past two years his health had been failing, but the end came rather suddenly, the deceased having visited his garden and gathered some Roses a short time previously. He leaves three sons, all of whom are well known in horticultural circles, viz., Mr. Edwin Beckett, V.M.H., head-gardener at Aldenham House, Elstree; Mr. Charles Beckett, head-gardener at Chilton, Hungerford; and Mr. Thomas Beckett, steward at Havering Park Farm, Romford.

FREDERICK PHIPPEN.

His many friends will regret to hear of the death of Mr. Frederick Phippen, which occurred on the 20th inst., from pneumonia, after a week's illness. Mr. Phippen, who was thirty-one years of age, had for many years represented Messrs. Jarman and Co. at the principal shows in the country. His bright, genial disposition attracted a large circle of friends. The funeral took place at Chard on Saturday, the 24th inst.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

AN exhibition of some variety and excellence was brought together on the 20th inst., the show being in the nature of a surprise. Its outstanding feature was the remarkable collections of British-grown fruit, five leading firms bringing of their best. Of its quality generally, the subjoined report will afford a good idea, though its high excellence is demonstrated by the fact that one gold Hogg medal, three gold medals and two silver Knightian medals—one for Grapes—were awarded. For the rest the double table group of winter-flowering Begonias from Messrs. Veitch, obviously—in view of the impending sale—the last of these from this eminent firm, showed these plants to perfection. Michaelmas Daisies from Lewisham have never been more finely or artistically displayed, while Carnations and Roses were also good. Only one or two Orchid groups were staged. The Orchid committee gave awards to two, and the floral committee to five, novelties, the fruit committee confirming an award of merit, after the usual tests of cooking and cropping, to a culinary Apple certificated in February last.

ORCHID COMMITTEE.

Present: J. Gurney Fowler, Esq. (chairman), Sir Harry J. Veitch, and Messrs. James O'Brien, W. Bolton, A. Dye, Gurney Wilson, E. H. Davidson, W. P. Bound, H. G. Alexander, J. E. Shill, C. H. Curtis, W. H. Hatcher, J. Charlesworth, J. Cypher, W. Cobb, F. J. Hanbury, R. A. Rolfe, C. J. Lucas, A. McBean, T. Armstrong, S. W. Flory, G. Hunter and Stuart H. Low.

Messrs. Charlesworth and Co., Hayward's Heath, Sussex, contributed a nice group, which comprised excellent varieties of *Odontoglossum crispum*, *Cattleya labiata* alba var. *Penelope*, *Dendrobium formosum giganteum* (very fine) and *D. Dearei* (both white-flowered sorts), *Brasso-Cattleya* Queen Alexandra, B.-C. *Moneta* (of rosy mauve colouring), *Cattleya Ena* (orange sepals and crimson lip) and *Lælio-Cattleya Elinor* (a very beautiful variety of rich orange tone).

T. J. Finnie, Esq., Claygate, showed a well-flowered example of *Cattleya labiata* with eight scapes of flowers, the plant making a fine show.

Messrs. J. and A. McBean, Cooksbridge, Sussex, showed *Cattleyas* in variety, *Odontiodas*, *Dendrobium Phalaenopsis*, *Lælio-Cattleya Cooperi* and *Cypripedium Rosettea*.

In a compact group from Messrs. Sander and Sons, St. Albans, we noted *Lælio-Cattleya Ophir* (rich golden yellow), *Cattleya Mantinii*, *C. Fabia* alba var. *Rex*, *C. Adula* var. *Aurora* and the very distinct *Coclogyne mooreana*, whose large white, yellow-lipped blossoms are borne on 18-inch-long stems. It is highly ornamental and beautiful.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. W. A. Binney, E. A. Bowles, J. Green, F. W. Harvey, W. J. Bean, W. Howe, G. Reuthe, J. W. Moorman, C. R. Fielder, J. F. McLeod, T. Stevenson, R. W. Wallace, R. C. Notcutt, J. Jennings, H. J. Jones, J. Dickson, C. Dixon, C. E. Pearson, W. Cuthbertson, J. T. Bennett-Poß, W. P. Thomson, E. H. Jenkins, W. G. Baker, A. Turner and G. Paul.

Messrs. James Veitch and Sons, Limited, Chelsea, displayed—positively for the last time—one of the finest groups of winter-flowering Begonias ever staged, even by this eminent firm. The group comprised a double table of these now indispensable subjects—indispensable from the standpoints of beauty, decorative value and winter flowering—and afforded a good idea of the work that has been accomplished in one direction of winter-flowering plants alone. Next to good spectacular display, excellence of culture commanded attention, and this at least is not likely to be surpassed. The varieties were not numerous, but they were good throughout. Of these, *Elatior*, reddish carmine, compact, free-flowering and brilliant in colour, was one of the best. *Exquisite*, salmon, white base; *Emita*, orange scarlet, large and free; *Optima*, pale orange, free and graceful, a fine decorative plant; *Mrs. Heal*, one of the best of the earlier sorts; *Fascination*, a compact-growing, orange-flowered *Optima*; and *The Gem*, a rich carmine crimson which in effect surpasses the earlier *Elatior*, were also included. The *Gem* is a remarkable plant, full of flower and bud, submitting to small pot culture, and therefore destined for a wide sphere of usefulness.

Messrs. W. Cutbush and Sons, Highgate, N., displayed *Liliums* grown from retarded bulbs, also *Hydrangeas*, soft-wooded *Heaths*, such as *Erica gracilis* and *E. nivalis*, whose crowd of snow white bells were very charming.

Mr. Elisha J. Hicks, Twyford, Berks, showed the new Hybrid Tea Rose Mrs. George Norwood, a variety remarkable for its fine perfume as well as good pink colour. Princess Mary (single crimson) was also fine.

Mr. James Box, Hayward's Heath, showed a nice group of *Asters*, particularly of the *Amellus* race, A. A. Framfield being very fine. *Erigeron Quakeress*, *Lobelia cardinalis*, *Cimicifuga simplex*, *Hippophaë rhamnoides*, *Aster Climax* and *Pernettya mucronata* alba were all good and showy.

Mr. L. R. Russell, Richmond, displayed Tree and other *Ivies* together, *Aucuba vera*, *Crataegus Pyracantha* *Lelandii*, *Clematises* of sorts, *Eurya latifolia* variegata and *Bamboos*.

Messrs. Barr and Sons, Covent Garden, W.C., contributed a nice lot of early flowering *Chrysanthemums*, also *Cyclamen cilicicum*, *C. neapolitanum*, *C. n. album*, together with such *Crocus* species as *nudiflorus longiflorus*,

zonatus, *speciosus*, *atlanticus* and *Hadriaticus*. These were very charming. New hybrid *Nerines* were in considerable variety and constituted a pretty feature. *Cornus canadensis* and *Schizostylis coccinea* were very good.

Messrs. Dobbie and Co., Edinburgh, showed *Collarette* *Dahlias* particularly finely, some from seeds sown in March and others from plants grown in the usual way. The whole afforded considerable variety and much colour beauty. *Balmoral* (deep cerise purple), *Eddystone* (scarlet), *Maidens* (yellow), *Diadem* (rosy mauve) and *Deveron* (rosy cerise and white collar) were all very fine.

Mr. G. Reuthe, Keston, Kent, had an interesting lot of bulbous plants, alpine and shrubs. Of the former, *Tropæolum tuberosum*, *Colchicum Parkinsonii*, *Crocus Hadriaticus*, *C. marathoniensis*, *C. zonatus* and *C. Clusii* were very beautiful. *Nerines* made a particularly good show, and *Helianthus orgyalis* was very good. A number of alpine were also shown.

Mr. J. J. Kettle, Corfe Mullen, near Wimborne, Dorset, had a display of *Violets La France*, Princess of Wales and *Ascania*, the latter a widely open flower of some distinctness.

Messrs. W. Wells, Limited, Merstham, showed early and exhibition *Chrysanthemums*, the former including Dorothy Dann (single bronze), Joan Edwards (amaranth), and Mrs. J. Fielding (bronze). Carnations Pink Sensation and Champion were also shown.

The Misses Hopkins, Shepperton-on-Thames, had a small group of alpine, such as *Primulas*, *Polygonum vacciniifolium*, *Convolvulus Cneorum*, *Plumbago Larpenæ* and others. *Viola Bowles* Black and other miniature sorts were also shown.

The Misses Price and Fyfe, East Grinstead, displayed Carnations and early and other *Chrysanthemums*. The Carnations were in some variety.

Mr. W. Wells, jun., Merstham, had a grouping of Michaelmas Daisies and *Phloxes*. *Aster cordifolius elegans* and *Phlox Iris* were both good.

Mr. Clarence Elliott, Stevenage, showed flowers of *Gentiana acaulis*, boxes of *Crocus speciosus*, *Potentilla willmottiana*, *Thymus carnosus*, *Achillea tomentosa* and *Phlox subulata Vivid*, all in good flower and several quite out of season.

Messrs. H. J. Jones, Limited, Lewisham, had a superbly arranged table of Michaelmas Daisies and *Chrysanthemums*, the vases and stands being handsome in the extreme. Of the former, Magnet, Henry Adams and Climax, in shades of light and dark blue, represented the best of the tallest of these at this season. *Sirius* (rose), *Mrs. Henage* (blue) and *Mrs. J. K. Holmes* (pink) were also good. Of the large-flowered *Chrysanthemums*, Bob Pulling (rich yellow), Mile. Elise Dorden, Betty Spark (pink) and Cranford Yellow were all excellent. A splendid group, artistically arranged.

Mr. Amos Perry, Enfield, showed hardy Ferns, in reality a collection of *Scolopendriums* representative of the many phases and variations of this remarkable tribe. It was perhaps one of the most representative collections ever staged.

Messrs. Stuart Low and Co., Enfield, had some nice groups of Carnations, of which Enchantress Supreme, Salmon King, Gorgeous, Mrs. Mackay Edgar (good shapely pink), Princess Dagmar (crimson) and Satin Robe were some of the more important.

Messrs. Allwood Brothers, Hayward's Heath, showed Carnations very finely, such as Champion, Princess Dagmar, Wivelsfield White, May Day and Salmon Enchantress being very fine.

A big stand of *Dahlias*, representative of all sections of the flower, was shown by Mr. W. Treseder, Cardiff.

Roses from Messrs. B. R. Cant, Colchester, included Comtesse du Cayla, Duchess of Wellington, Gottfried Keller, Lyon Rose, White Maman Cochet, Irish Elegance, Snow Queen, Augustus Hartman, Lady Hillingdon and Rayon d'Or. A superb gathering of these popular flowers.

Excellent Carnations were arranged by Mr. C. Engelmann, White Enchantress, Enchantress Supreme, Scarlet Carola, White Wonder and Lady Northcliffe all being good. Triumph and Elektra were also noted.

Messrs. H. B. May and Sons, Edmonton, displayed Begonias, Bouvardias, Crotons, Ferns, Statice and Cyclamen. A grand specimen of *Drynaria quercifolia* was in the centre of a fine group.

FRUIT AND VEGETABLE COMMITTEE.

Present: J. Cheal, Esq. (chairman), and Messrs. W. Bates, J. W. Willard, W. Pope, H. Markham, Owen Thomas, H. J. Wright, A. Bullock, Thomas Coomber, G. Wythes, E. A. Bunyard, J. Harrison, G. G. A. Nix, F. G. Treseder and A. R. Allan.

There were several magnificent collections of fruit staged, and the fact that one gold Hogg medal and three gold medals were awarded proclaimed their excellence. Indeed, it is not too much to say that finer produce has only rarely, if ever, been staged.

The most extensive collection was that from Messrs. George Bunyard and Co., Maidstone, this occupying a table running the entire length of the hall on its northern side. Some 200 varieties of Apples and Pears were staged by this well-known firm, the fruits being generally of high excellence, though we incline to the view that Messrs. Bunyard have staged examples which exhibited better finish and finer colour. Some of the Pears were of huge size; one fruit of Pear Marie Benoist was said to weigh 2½ lb. Of this variety a dozen giant fruits were arranged. Other fine varieties included Beurré Diel, Belle de Arbrès, Uvedale's St. Germain, Beurré Baltet Père—a basket contained a dozen giants of high merit—Catillac, Directeur Hardy and Durondeau. Of Apples of more than ordinary merit we selected Egremont Russet, McIndoe's Russet, Norfolk Beauty (of pale yellow colour), Emperor Alexander, Mère du Ménage (very large), Cox's Orange Pippin, Charles

Ross, Rev. W. Wilks, Brownlee's Russet, Bramley's Seedling, Lane's Prince Albert (a very nice dish), Cellini Pippin and Allington Pippin. Gold Hogg medal.

Messrs. Cannell and Sons, Eynsford, Kent, arranged a particularly attractive and highly meritorious collection of 146 varieties of Apples and Pears, the whole remarkable for size, finish and high cultural excellence. Indeed, not a few of the examples were of outstanding merit and were greatly admired. Of Apples we noted Bietigheimer Red, Baron Wolseley, Blue Pearmain (carrying a Grape-like bloom on its fruits, which was distinctly ornamental), Norfolk Beauty (perhaps the finest of the yellow-skinned varieties), Annie Elizabeth, Gascoyne's Seedling, Wellington (a superb lot) and Beauty of Kent. In addition, the best known sorts—Bramley's Seedling, Peasgood's Nonsuch, Cox's Orange Pippin, Ribston and others—were very fine. The best dishes of Pears were those of Conference, Doyenné du Comice, Beurré Bosc, Duchesse d'Angoulême, Princess, Pitmaston Duchess, Late Orange and Beurré Diel. Gold medal.

Messrs. J. Cheal and Sons, Crawley, set up a very attractive collection of 125 dishes of Apples and Pears, and here, too, high cultural merit, colour and good finish dominated the whole. We were impressed with the refined look of the fruits in this collection, the whole being well presented. The best examples of Apples were Lane's Prince Albert, Egremont Russet, Allington Pippin, Gascoyne's Scarlet (very striking), Golden Noble, Royal Jubilee, Sandringham, Crawley Beauty, Brownlee's Russet, Blenheim Orange, Beauty of Stoke, Stirling Castle, The Queen, Beauty of Kent, Newton Wonder and Cox's Orange Pippin. The finer dishes of Pears were Doyenné du Comice, Conference, General Todleben, Beurré Alexandre Lucas and Beurré Clairgeau, the whole making a highly attractive exhibit. Gold medal.

The other gold medal collection came from Mr. R. C. Notcutt, Woodbridge, who also arranged a somewhat extensive table of fruits. These latter were generally of large size; and while for the most part more finely coloured than was the case in some of the other collections, there was lacking that degree of finish so conspicuous elsewhere. There were, however, many handsome dishes. Of Pears, perhaps the more striking were Doyenné du Comice, Louise Bonne of Jersey, Duchesse d'Angoulême, Beurré Bosc, Pitmaston Duchess, Beurré Superfin and Winter Nelis; of Apples, Charles Ross, Royal Jubilee, Worcester Pearmain, Chelmsford Wonder, Bismarck, Lane's Prince Albert, Newton Wonder, Allington Pippin, Frogmore Prolific, and Hollandbury, which was very finely coloured.

Messrs. J. Carter and Co., Raynes Park, S.W., received a silver Banksian medal for a collection of pot-grown Capsicums, some of which were of a highly ornamental character. Perhaps the more striking was Elephant's Trunk, of rich red colour, the huge pendent fruits being very attractive. Others were Golden Dawn, Celestial (red, erect fruits), Long Yellow (with tapering yellow fruits) and Sweet Spanish (whose big, drooping fruits are coloured a glossy reddish scarlet).

Charles Bayer, Esq., Tewkesbury Lodge, Forest Hill, received a silver Knightian medal for a collection of Grapes, the varieties including Gros Colmar, Muscat of Alexandria, Appley Towers, Black Alicante and Chasselas Napoleon, several bunches of each being staged.

Messrs. Laxton Brothers, Bedford, were also the recipients of a silver Knightian medal for a capital collection of Apples displayed in a most artistic manner. The collection was less extensive than some, yet it served by branched stands and in other ways to demonstrate the ornamental as well as the utilitarian value of these fruits, the whole of which were in the highest perfection. Varieties, too, were numerous and good, though we considered such as Newton Wonder, Lane's Prince Albert, Cox's Orange Pippin, Charles Ross, Rival, Bramley's Seedling and Ribston Pippin of outstanding merit and beauty.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the floral committee was held in the Essex Hall, Essex Street, Strand, on Monday, the 19th inst., when a few varieties only were staged for awards. Those that received recognition from the committee were as follow:

Dorothy.—A medium-sized yellow reflexed Japanese variety with broad florets and good substance. The colour is very rich. Should prove a good market variety. Shown by Mr. Norman Davis, Framfield, Sussex. First-class certificate.

Elfrida.—A large and beautifully shaped single, the broad florets overlapping each other well. The colour is a sort of reddish bronzy yellow, with old gold shading towards the tips of the petals. Shown by Messrs. Cragg, Harrison and Cragg, Heston. First-class certificate.

James Stredwick.—A very large reflexed Japanese, the blooms showing a wonderful depth. The colour is a pleasing deep shade of old rose with a suspicion of crimson in the centre. Shown by Messrs. J. Stredwick and Sons, St. Leonards. First-class certificate.

Earl Roberts.—A large Japanese variety with broad, reflexed petals. The colour of these is bright rich crimson with gold reverse. Shown by Mr. G. Mileham, Evelyn House Gardens, Leatherhead. Award for colour.

A splendid collection of well-finished Grapes was shown by Mr. E. C. Wickens, gardener to C. Bayer, Esq., Tewkesbury Lodge, Forest Hill. These comprised fine bunches of Chasselas Napoleon, Appley Towers, Black Alicante, Muscat of Alexandria and Gros Colmar. A silver-gilt medal was awarded this excellent exhibit.

THE GARDEN.

No. 2242.—VOL. LXXVIII.

NOVEMBER 7, 1914.

NOTES OF THE WEEK.

Help for Our Wounded Soldiers.—In these days, when it is the duty of every British citizen to make some sacrifice on behalf of the Empire, many calls are made upon the purses of those who are unable to take an active part in the conflict. One of the most deserving of these calls is now made by the Ambulance Department of the Order of St. John of Jerusalem in England. A special committee of ladies of the Order has been formed, and they are now appealing for shilling subscriptions to enable them to carry on their work of relief. Already 150 hospitals and convalescent homes have been established, 209 doctors and nurses have been sent to the Front, numerous bales of medical stores and supplies have been sent to the sick and wounded, and a number of motor ambulances are now being despatched to the Front. We appeal to our readers to subscribe as liberally as they can to the funds, and so help to relieve the sufferings of our soldiers who have been wounded while fighting for them. All subscriptions should be sent to the secretary, Ambulance Department, Marconi House, Strand, London, W.C. Ladies willing to collect shillings should send in their names to that address.

A Good Shrub for Sandy Soil.—The illustration on this page represents a flowering spray of *Cistus Loretii*, one of the most beautiful of all the Rock Roses and a shrub that will thrive in sandy soil. This *Cistus* is of hybrid origin, its parents being *C. ladaniferus maculatus* and *C. monspeliensis*. It grows very quickly, and eventually forms a graceful, spreading bush 5 feet or more high. Its flowers, which are produced with great freedom towards the end of the summer, are pure white, with a deep crimson maroon blotch at the base of each petal. Although individual flowers last only one day, a large number open each morning, and so maintain the display. In nurseries *C. Loretii* is often known as *C. cyprius*. It may be planted at any time during November or early December, or during February and the first week or two of March.

Aquilegas in Pots.—The hybrid Columbines are among the most ornamental and decorative plants for beds and borders, but seldom does one see them used for decorating the greenhouse in the spring. The largest crowns should be carefully lifted now and transferred to pots of a suitable

growth re-commences in the spring they should be brought into a warm house to flower. Their value as cut flowers needs no mentioning, and in pots, mixed with light foliage plants, they will be found equally as serviceable.

Sir David Prain's Son Killed in Action.—It was with deep regret that we noted the name of Lieutenant T. Prain of the Leicestershire Regiment among the list of officers killed in action that was published on October 30. Lieutenant

form of enquiry which is being sent out from there with a view to obtaining more definite particulars about American Gooseberry mildew. Twelve simple questions are asked on the form, answers to which are to be filled in and the form returned to the Director at Wisley. Professor Keeble will be glad if all growers who fail to receive one of these forms will communicate with him at the Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey.

Seedlings of the Willow.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. Fraser remarked that it had been reported that Willow seed rarely or never germinates, but he produced considerable evidence in the form of seedlings to show the contrary was the case. A constant supply of moisture and the absence of competition with tall herbaceous plants are necessary to the success of the young Willow seedlings, but given these conditions the seed germinates readily when fresh. He had found seedlings of *Salix repens* (which will germinate within forty-eight hours of sowing), *S. alba*, *S. viminalis*, *S. Lapponum*, *S. Caprea*, *S. cinerea*, *S. aurita*, *S. nigricans*, *S. phylicifolia*, *S. Arbuscula* and *S. lanata*. He showed beautifully dried specimens of all but the last of these.

Mr. Leonard Sutton, who has been selected for the coming year as Mayor of the Borough of Reading, is the youngest son of the late Mr. Martin Hope Sutton and the second senior partner of the firm of Sutton and Sons, Reading. He was born in 1863 and was educated at Wellington College and the Royal Agricultural College, Cirencester. Mr. Sutton is a Fellow of the Linnean Society, and has been closely connected with agricultural education since leaving Cirencester. He has been for some years chairman of the Reading Education Committee, and is also a

A FLOWERING SHOOT OF *CISTUS LORETII*, A GOOD SHRUB FOR SANDY SOIL.

Prain was, we understand, the only child of Lieutenant-Colonel Sir David Prain, I.M.S., C.M.G., F.R.S., &c., Director of the Royal Botanic Gardens, Kew, and we feel sure that the sympathies of all our readers, and Kewites in particular, will be extended to Sir David and Lady Prain in their great bereavement.

Wisley, and American Gooseberry Mildew.—Professor Keeble, Director of the Royal Horticultural Society's Gardens at Wisley, sends us a

member of the Council of the Reading University College, being chairman of its Advisory Farm Committee, and was appointed by the college as a member of the deputation to visit agricultural colleges in the United States and Canada in 1910. Mr. Sutton is a member of the Berkshire County Association. He has two sons serving as second lieutenants with His Majesty's Forces in the Berkshire Yeomanry and the Royal Sussex Regiment (7th Battalion)

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Gardeners and the Army.—Having received numerous enquiries as to the procedure gardeners have to take with their State Insurance cards on their enlistment in His Majesty's Forces during the war, I have appended a few instructions for the benefit of your readers who may wish to know how to proceed on enlistment. They should procure their insurance cards from their employers, stamped to the date of leaving their employment only, and send them to their respective societies. By doing this they will be entitled, on discharge to civilian life, to full benefits under the Act. Gardeners while serving in the Navy or Army will be known as B Class, and pay a contribution of 3d. per week, of which 1½d. will

Double-Flowered Peach Fruiting.—In answer to Mr. Turner's question, my flowering Peach is the pink one.—G. E. JEANS.

Moss on Tennis Court.—Will anyone advise how to destroy moss on a sand court and prevent its recurrence? Weed-killer has been tried without success.—G. J.

Buddleia Colvillei Flowering in Autumn.—In compliance with your request for information as to *Buddleia Colvillei* flowering now, there is a fine plant of it in this neighbourhood in flower, the first time it has given second blooms. The late Mr. W. E. Gumbleton had it for a great many years, but it hardly ever gave a bloom at any season, for its very vigorous growth was badly ripened and never pruned in any way, to which I attribute its barren condition. It has never suffered from frost in the garden I refer to, and bloomed a short time after it was planted.—(Captain) J. H. POE, D.L., *Riverston, Nenagh*.

A FINE SPECIMEN OF THE MEXICAN ORANGE (*CHOISYA TERNATA*) AT THE CEDARS, HALSTEAD, ESSEX.

be deducted from their pay. They still remain members of their societies, and on their return to civil employment their cards will again be stamped with 7d. stamps.—A. C. HILL, *Secretary of the United Horticultural Benefit and Provident Society*.

Late Sowing of Hardy Annuals.—Owing to the extreme dryness of the weather in June this year, I kept back seedlings of Ten-week Stocks in pots which were not sown until May, and did not plant them until July, when we had some showers. These plants began to bloom in August and have gone on till now, growing more vigorously and flowering far better than I ever saw them earlier in the summer. So many gardens look bare and shabby in August that I wonder more is not done with late-sown annuals to brighten up patches of ground in the borders where early seedlings have gone out of flower.—F. H. CASE, *Bishop's Waltham*.

Quince Jelly.—With the heavy crop of Quinces this year, a pleasant way of utilising them is to convert them into jelly, which is quite a simple process. Peel, core and slice the fruit into small pieces. Boil for two and a-half hours in water sufficient to float the fruit. Strain the liquid through a jelly bag, and to every pint of liquid add a pound of sugar (good quality lump). Boil again until the whole is a thick jelly. Place in small pots, cover the jelly with a piece of white paper soaked in brandy as a means of preventing mould growing on the jelly, and securely fasten down with air-tight paper.—E. MOLYNEUX.

Rose Excelsa.—I am pleased to see, in the issue for October 24, page 515, that Mr. M. H. Walsh has been honoured so highly for raising this wichuraiana Rose. I am sure it will take the place of Crimson Rambler, not because it is superior in colour to that old favourite, but because it is so immune from mildew, which

is the weakness of Crimson Rambler. *Excelsa* is a grand Rose in every way.—E. M. [We think that, apart from its freedom from mildew, *Excelsa* is superior to Crimson Rambler, as the flowers do not turn magenta blue with age.—ED.]

A Good Specimen of the Mexican Orange.—The accompanying illustration of the Mexican Orange, *Choisya ternata*, is from a photograph kindly sent us by Miss Philbrick, The Cedars, Halstead, Essex, the president of the National Sweet Pea Society for 1915. This is one of the most beautiful of our flowering shrubs, its umbels of fragrant white blossoms opening usually in May, to be followed in some years by a less bountiful display in September or October. It needs a situation screened from north or east winds and soil that is well drained, and in very severe weather should have an old mat or two fixed round it. In writing, Miss Philbrick states that the shrub illustrated is growing beside the front door of her residence, and that it is 7 feet high and about five feet in diameter. It has been planted about six years.

Government Trading in Ireland.—About a year ago evidence was placed before the Council of the Horticultural Trades Association of Great Britain and Ireland that the Irish Board of Agriculture was, through its county committees, purchasing, at the lowest wholesale rates they could obtain, all sorts of nursery stock. This was being divided up and passed on to large and small land owners and holders. It was considered an interference with the legitimate trade of Irish and other nurserymen, and a remonstrance was sent to the proper quarter. A reply was received to the effect that the intention of the procedure was to encourage small farmers and landowners to go in for fruit culture. To this, strictly carried out, there could possibly be no great objection. Again, however, in 1914 the old unfair game is being played. Numerous county committees of agriculture are sending round for estimates for not only fruit trees, but forest trees—Scotch Pine, Austrian Pine, Elm, Larch, Spruce Fir, Ash and Birch—in various sizes; also plants for cover, evergreen and flowering shrubs and Roses. Surely these are not all required to encourage the small farmer and landowner to go in for fruit culture! One correspondent informs me that "Not only cottagers, but noblemen can get supplies through their county committees," and that "the practice is general throughout nearly the whole of Ireland." I think the case wants to be stated in other than a private trade journal. Therefore I take the liberty of sending this note for publication in the columns of THE GARDEN. Publicity is often the first step towards reform.—W. CUTHBERTSON, *President, Horticultural Trades Association*.

Propagating Perpetual-Flowering Carnations. It is true that, as pointed out by Mr. Brotherston (see page 517), a pronounced diversity of opinion exists as to the most suitable time for propagating these plants. For a considerable number of years, from the time the variety Miss Joliffe was in its prime onwards, I aimed at getting a good batch of cuttings rooted in autumn, and, provided these were of the right stamp, all was well. I cannot, however, agree that at that season they root with "more facility" than at other times. The correct type of cutting will root well at almost any time, but I have never yet seen the finest cutting available in January capable of equalling, much less overtaking, one of equal quality rooted in September

or October. The fact is, it cannot be done. Some plants may be "forced," but a Carnation only at its peril. The plant rooted and potted in October is possessed of a root economy far in advance of that rooted in January, and will have made two or three good breaks. But if these are useful in their way, the January and February rooted stock is invaluable, since it is from such that the grower obtains his high-class midwinter flowers and top prices. Hence both seasons have their value, and the gardener, commercial or private, who requires a long succession of high-class flowers will be well advised to embrace both. The "heel" cutting I gave up some years ago in favour of the joint-made one, the latter making much the better plant. As a rooting medium, there is nothing to equal well-washed sand, and in a 2-inch-deep bed of it there should be few losses if the cuttings are of the right sort. The amateur who has no frame should procure a box and cover it with a sheet of glass. A box 18 inches by 12 inches by 9 inches will take quite a number of pots, and those of 5 inches diameter will accommodate ten or a dozen cuttings easily. Use well-drained pots, with a little soil or Cocoanut fibre above and the rest pure sand, and one has the best means available for the successful propagation of these plants.—E. H. JENKINS.

— Mr. R. P. Brotherston, in his article on Perpetual-flowering Carnations on page 517 of THE GARDEN for October 24, raises an interesting point about the proper time to take the cuttings, and also the sort of plants which are used for stock purposes. As regards the question of propagation in the autumn or spring, I am decidedly in favour of the former, as I have proved that these make the best plants. Some varieties make roots much quicker and surer than others, and when rooted are much faster growing. These, I think, are the ones that can be propagated in January and onwards, and will make as fine plants by the autumn as those struck earlier. I have tried several different rooting mediums, and the one I have had the fewest failures with is two parts brown sand, one part finely sifted loam and one part leaf-soil. There is thus a preponderance of sand, and the leaf-soil and loam help to bind it together and provide a little nourishment throughout the winter months. We place the cuttings singly in 2-inch pots, make up a mild hot-bed, and plunge the pots in Cocoanut fibre refuse. The cuttings are well watered in, and in from ten to fourteen days some of them are ready to come out of the fibre. They are wintered on a shelf in a cool greenhouse, and as soon as growth commences in the New Year they are pinched and potted on into 3½-inch pots, then into 5-inch, and finally into 7-inch. The first pinching produces four or five shoots, and is much better, as Mr. Brotherston suggests, deferred until January. As regards the type of plant for stock purposes, I have found the following a good way: About April take a few plants of each variety, and either plant them out on a north border or stand them out in the pots. These plants will continue flowering all the summer, and if kept cut will produce an abundant crop of clean, healthy cuttings by the autumn. These can be taken off and struck as I have suggested. A north border is not absolutely necessary, but in a summer like the past would be preferable. I might say here that we usually stand about half our plants outside during the summer, and those left in are again potted on into 8-inch pots in March, and continue to give

abundant supplies of bloom all through the summer months. I once asked a gardener friend who grew these plants well when he struck his cuttings. His reply was: "All the year round." I thought that opened up a still wider field.—R. W. THATCHER, *Carlton Park Gardens, Market Harborough.*

IN A HAMPSHIRE GARDEN.

NOTES ON THE NEWER DECORATIVE ROSES.

LOOKING back over the season of 1914, one can but feel that it has been a wonderful Rose season—to all but the exhibitor, to whom it was probably disappointing, disappointing, though, chiefly by reason of the fact that the Roses did not come at the *right time*. Here in Hampshire the Roses were too early for the shows, and the first blooms were all over before June was out; in fact, mine were at their best between June 15 and June 22; but leaving the exhibition point of view out of the question, it has undoubtedly been an exceptional season, suffering at times from a lack of rain, but for general quality and quantity of flowers unsurpassed in my recollection. Aphides troubled us but little, though they were never allowed to get a hold. Abol, which I always use, was applied early; but I only used half the quantity that was required last year. Mildew, generally rather troublesome, was tackled with Seride, which is quite good for the purpose, and only quite recently has the disease been at all prevalent. Black spot has not been so apparent as in previous years. Formaldehyde was used as recommended by Dr. Waddell, and while I cannot say it is a cure, the disease has been far less destructive, and only those plants that are particularly subject to it, such as the Pernetianas and their hybrids, have shown traces. Some, such as Prince de Bulgarie and Hugh Dickson, that were badly infected last year, have this year practically escaped. I have been quite free from any other pest.

Where all Roses have been so good it is difficult to pick out the best, but the following have, I think, stood out as being very fine. We are gradually getting some good yellows, and the season has suited this colour, being, on the whole, while sunny, not too much so.

Melody has been particularly beautiful here. I have about fifteen plants of it, ten in one bed, so that my experience is not the result of the behaviour of one or two plants. It is very free-flowering, of good colour, though not very large even when fully out, and makes a good button-hole flower in the young stage. It is deliciously scented, a good grower of medium rather than vigorous growth, and is more nearly allied to a Tea than to a Hybrid Tea. It is one of the best of Roses for table decoration, lasts well in water, and its foliage forms a fine contrast to the pale yellow (with a deeper centre) of its flowers. It came through the winter all right, and is a great acquisition to garden and decorative Roses. It has made plenty of good growth, and is altogether a better Rose than I was inclined to give it credit for last year. Messrs. Alex. Dickson and Sons of Newtownards are the raisers, and when better known it should become very popular. To anyone who is desirous of planting a bed of a good yellow Rose, I can confidently recommend him or her to try Melody.

Mme. C. Lutaud, raised by M. Pernet-Ducher and sent out in 1912, is another very fine flower of rather more substance and carrying its flowers on longer footstalks perhaps than Melody. It could be described as a pointed form of Marquise de Sinety. It is a fine grower, with curiously serrated foliage of a good bronze shade, and has been very fine with me this autumn. It is a Hybrid Tea, but not of the Soleil d'Or race, and so far has not suffered at all from black spot, that dark blot on the escutcheon of all the Pernetiana Roses. It is a Rose to make a note of, and should certainly be tried by all who have not got it. A good dark chrome yellow, with the outside petals sometimes stained rosy scarlet and carmine, it lasts well when out, and does not fade so quickly as most yellows.

Mrs. Ambrose Ricardo.—Sent out this year by Messrs. S. McGredy and Son of Portadown, Ireland. Of all the new Roses that I have tried this year—and I have had a good many not yet in commerce—I am inclined to say this is the finest introduction. It is certainly the largest yellow I know, and very nearly the largest Rose; exquisitely scented, of fine form, right up to the highest exhibition standard, and at the same time a good decorative plant. The colour is a good shade of yellow, with a deep, almost buff, centre of the shape of Mrs. Amy Hammond. It is a good grower, of good habit that is branching and not too vigorous, and free-flowering. The raisers were, unfortunately, unable to exhibit any of their Roses for the gold medal this year, and so I am afraid Mrs. Ambrose Ricardo will miss that distinction; but few Roses deserve it better. It has been the surprise of the year to me, and although I liked it when it was exhibited in 1913, it was not then shown in character. It is a very much better Rose than the blooms exhibited would have led one to expect, and I am inclined to think it is the best Rose these raisers have yet given us. It keeps its colour well, and lasts a long time both cut and on the plant. The trade as well as the amateur should make a note of this Rose, and get it if they have not already done so.

The foregoing three yellows are all Hybrid Teas. The best yellow Tea is undoubtedly (from a bedding point of view)

Lady Hillingdon. This Rose improves every year with me, and a small bed of fifteen plants has never been without flowers since June, and even now in October has been as full of flower as at any time during the whole season. There is no other yellow quite so dense in colour. It is really a deep apricot. The scent is very sweet and fruity in character. The foliage and habit of the plant are good. Its only fault is that the footstalks are too thin and the flower generally hangs its head; but there is no denying its beauty, and the glow of colour is intense. With foliage of Rosa rubrifolia or its own it makes a charming decoration either for vase or table, and although it is a Tea it is not so tender as some. The May frosts this year did not injure it nearly so much as they did some of its supposed hardier cousins, the Hybrid Teas. For some reason that I cannot understand there is a prejudice against this Rose which I have noted on more than one occasion. It will make a far more satisfactory and more permanent bed than Rayon d'Or, which Rose I overheard a nurseryman who ought to have known better recommending in preference to it.

Southampton. HERBERT E. MOLYNEUX.

(To be continued.)

ROSES IN OCTOBER.

LAST week a gardening friend asked what, in our opinion, was the greatest improvement that had been effected among Roses during the last twelve or fifteen years? For answer we took him into the garden and showed him Roses blooming freely, not the odd one or two caricatures of Roses that sometimes pass muster for the Queen of Flowers, but large, well-formed, fragrant blooms that would not, many of them, have disgraced a June garden. No doubt the mild, open weather we have experienced in Essex has had something to do with the quality of the flowers; but, mistake it not, the greatest progress has, in recent years, been in the lengthened period of flowering—from June until well into October or even November.

late in starting to blow, but who retains her deep blushes until her heart is hardened by the winter frost. Last year this did not happen until after Christmas.

Having assorted our October Roses so far, we find so many clamouring for the next position that it is impossible to allocate it to any one. They must be content to come in the order that we jotted them down in a much-used, and our friend suggested much-abused, notebook. Here, then, in that order, we present them: Mrs. Arthur Munt, glorious blooms of creamy white; Mrs. Aaron Ward, white, with deep yellow base; Lady Pirrie, a wonderful shade of apricot pink; Hugo Roller, deep cream, edged carmine; Mrs. E. J. Holland, a rather peculiar shade of old rose, but exquisite in form; Sunburst, glorious nankeen yellow, better than in hot weather; Mrs. Herbert Stevens, the dainty, refined lady of all the white

WINTER - FLOWERING BEGONIAS.

THE magnificent group of these Begonias contributed by Messrs. Veitch to the meeting of the Royal Horticultural Society on October 20 must have aroused in many feelings of pride not unmingled with regret. The reason for a natural feeling of pride is that the whole of this splendid section of flowering plants has been developed from comparatively small beginnings within the last thirty years or so, and all must be credited to British horticulturists. For many years, commencing with the variety John Heal, Messrs. Veitch were alone in producing new kinds; but of late Messrs. Clibran of Altrincham have come prominently to the fore and given us annually some really good things.

There is one point of difference between the productions of the two firms, and that is that most of Messrs. Clibran's Begonias have either double or semi-double flowers, whereas those raised by Messrs. Veitch, or, rather, by their enthusiastic grower, Mr. John Heal, consist for the most part of varieties with single blossoms. The later novelties from this last-named source approach much more nearly the members of the tuberous-rooted section than did the earlier crosses, in whose production Begonia socotrana has played a part. This was especially notable in the case of the variety Optima, which attracted more general attention than any other kind shown on October 20. This variety is of a good bold, yet sturdy habit, and the flowers, which are large and well shaped, are of a pale yellowish salmon colour. Other new or comparatively new varieties of this section, several of which have been given awards of merit by the Royal Horticultural Society, and most, if not all, of which were shown on the above-mentioned date, are Acquisition, salmon rose; Emita, rich orange scarlet, very bright and fine; Epirus, rosy pink; Exquisite, salmon pink, light centre; Fascination, orange salmon; Her Majesty, salmon yellow; Optima, referred to above; Rosalind, rose; and Syros, pale salmon, dark foliage and late in flowering.

The regret alluded to in the early part of this article was that we had seen the last of Messrs. Veitch's wonderful collections of these charming flowers, which for

years have done so much to brighten up the Royal Horticultural Society's Hall at a time when bright-coloured blossoms are none too plentiful. They are usually referred to as winter-flowering Begonias, but perhaps late autumn and early winter would be nearer the mark. Even before the group of these flowers above alluded to was exhibited, the announcement was made that the entire stock would be disposed of by auction just one week later, which sale has now taken place. A perusal of the catalogue serves to show that there was at Feltham (where these plants were grown) a considerable number of these beautiful Begonias, consisting altogether of about 4,800 plants. The variety Optima would appear to be as much appreciated by Mr. Heal as it was by the visitors to the hall, for about 600 plants of this were announced in the catalogue.

It is by no means alone in Begonias that Messrs. Veitch's retirement will be regretted, for although

BLOOMS OF ROSE JAMES COEY, A BEAUTIFUL PALE YELLOW HYBRID TEA VARIETY FOR SUMMER AND AUTUMN.

It may be of interest to briefly record those varieties which, during the closing days of October, gave us such pleasure. Place of honour must be given to Gloire de Dijon. In mid-May, before the last of the Tulips had departed, this started to flower, and has not ceased since, nor is it likely to do so if the weather keeps mild. Exhibitors, of course, will say the flowers are of poor shape, but its vigorous habit, quaint buff colour, delicious Tea fragrance and freedom of flowering will ever retain for it a deep niche in our affection. Next must come General Macarthur, a crimson bedder as fragrant as it is free. Mme. Leon Pain, with its pink, shaded apricot flowers, is placed third; its habit is so good, too, for beds. On a level with these three we must place the Polyantha varieties Jessie, crimson scarlet; Phyllis, bright pink; Orleans, rose pink; and Katherine Zeimet, white. And we give place of honour in this quartet to Jessie, a dainty little lady who is rather

Roses; White Killarney, a poor Rose in the summer, but good in the autumn, not really pure white; Irish Fireflame and Irish Elegance, a pair of singles that ought to be in every garden; Mrs. J. Laing, a Hybrid Perpetual that always mildews badly in the autumn, but we must have it for the fragrance of its pink flowers; Betty, a fine garden Rose; Mrs. Wakefield Christie Miller, pink, with deep glowing rose reverse; Mrs. Walter Easlea, fragrant, crimson scarlet; Mrs. Edward Powell, rich crimson; Gustave Regis, the button-hole Rose, nankeen yellow buds; Frances Charteris Seton, very fragrant and of exquisite shape; James Coey, soft yellow, almost the shade of Maréchal Niel (see illustration); Pharisæer, rather tall and free, silvery pink; Mme. Abel Chatenay, and Duchess of Wellington, rich yellow. The last-named does not open too well when the weather is wet, but, given a few reasonably dry October days, it is superb.

the fruit tree traditions may still be upheld from the historic soil of Langley, we shall greatly miss the charming stove and greenhouse plants, which were rarely, if ever, absent from the fortnightly meetings; while one can scarcely realise the loss to horticulture in general by the dispersal of the Coombe Wood collection. With the great sale of fruit trees at Feltham in November, we see, I understand, almost the final act of the passing of a great firm, a firm that will be missed by every horticulturist in the kingdom.

Though I have departed somewhat from the heading of this article, a few words may well be spared Messrs. Clibran's race of these Begonias, in which double and semi-double flowers predominate. Particularly striking are some of their newer kinds, notably Empress, salmon red; Matchless, salmon; Picotee, orange salmon; Radiant, brilliant cerise crimson; Vivid, bright scarlet; and Vulcan, rich crimson.

H. P.

MUSHROOMS ALL THE YEAR ROUND.

It may, perhaps, be interesting to other readers if I describe how I grew Mushrooms all the year round in a large stone-built shed which was very cold. To keep the frost from getting at Potatoes stored in the shed, I had to fasten mats and sacks close inside a large window in the front wall, and the Potatoes were covered with a large thickness of straw and garden mats. Having the manure from three or four stable-fed carriage horses, I placed this on the floor of a very large open-fronted cart shed in the stable yard. The manure was spread out thinly and not allowed to get very warm at any time. In about three or four weeks' time there was thoroughly mixed with the manure well-chopped decayed turf, taken off a meadow, in the proportion of about one barrowful of turf to about three barrowfuls of the manure.

When this was well mixed together, it was taken into the shed and placed on a good thick foundation made with the straw shaken out from the manure. The bed would be about four feet wide and about two and a-half feet deep. The manure when spread out on the bed was well trodden down. The bed never became hot, so that in the course of a few days it was planted with the best spawn, broken in lumps as large as ducks' eggs, these being placed about six inches apart. All the spawn was planted about three inches deep with a garden trowel, and the manure taken out of the holes for the spawn was then replaced and rammed down firmly. The temperature of the bed was tested by means of a few pieces of Bean sticks pushed well into the bed, and the heat tested by the hand.

In a few days after spawning the bed, if the heat was not rising, there was placed on the top about four inches of decayed turf, which was made wet by watering it with warm water from a rosed watering-pot. Before putting it on the bed this soil was well beaten down with the back of a garden spade. Then for the winter crops about a foot thick of best hay was placed over the bed. Hay keeps the bed much warmer than a straw covering. From beds made like this I always got fine crops of Mushrooms. The Mushroom-beds in the winter were very seldom watered, when in full bearing, but towards the early summer and onwards they were given a

THE LAMB'S-EAR PLANT (STACHYS LANATA) GROWING IN THE LOWER COURSES OF A DRY WALL.

fair soaking of warm water in which was put a small quantity of table salt. At our local vegetable and flower show held here in July, as I happened to have a Mushroom-bed in full bearing, I entered a class for twelve dishes of vegetables, and also one for nine dishes. In each collection I had a fine plate of two entire clumps of nice pink Mushrooms. Each clump was lifted from its bed and placed upside down on the large dinner plates, which the Mushrooms nearly covered. I was fortunate in getting first for the twelve dishes, also for the nine dishes. I generally had more Mushrooms than my employer wanted for his family, so the surplus was given to his friend.

Newport, Mon.

R. GIDDING

THE LAMB'S-EAR PLANT.

A PLANT of unusual aspect, and one that is not frequently met with, is the so-called Lamb's-ear Plant, known to botanists under the name of *Stachys lanata*. Its unique appearance is due to the thick, woolly foliage and stems, which are of a silvery white hue, and provide a welcome change during the summer months from the glaring colours of the surrounding flowers. It is a plant that will thrive with a modicum of soil, and even that need be only of the poorest character. For this reason it is admirably adapted for planting in the lower courses of a dry wall, as shown in the accompanying illustration, where it is quite at home and has formed an attractive and interesting specimen.

RESTORING VINES TO HEALTH.

BEFORE deciding on the course to take with the object of restoring sickly Vines to good health, it is well, first, to find out, if possible, what has been the cause of failure, because if it is the result, say, of an attack of red spider, thrip, mealy bug or any other pest injurious to the Vine, it is obviously useless to incur the expense and labour of replanting in new soil before these pests are destroyed. It may be that none of the above causes has operated to bring about the ill-health of the Vines, but rather that it has been caused by the exhausted condition of the soil, defective drainage, or that the main roots are deeply embedded in uncongenial subsoil. This can only be ascertained by examining the roots and the condition of the border, which we will now proceed to do, say, at the end of October or at any time during the winter, but the earlier the better after the time mentioned. Many Vines are planted in borders which are partly outside and partly inside, others in outdoor borders only, and others, again, in inside borders only. The work of renewing the borders is much the same in each case. Taking the double border as an example and treating the inside of it first,

the first thing to do is to clear the vinery of all plants or any other portable article likely to impede the progress of the work, and then cut a trench 18 inches wide the whole length of the border and as deep as the bottom of the border, say, 2½ feet. The side of the trench next to the Vines must be at least 8 feet distant from them. The whole of the soil in the trench, down to the drainage at the bottom, should be wheeled away. All roots that are come in contact with in forming this trench should be cut through with a knife. Having cleared the trench of all the soil, the next thing to do is to purchase a well-made five tined fork, and gradually and carefully to work away the soil from the border into the trench until we

reach within 2½ feet or 3 feet of the stems of the Vines. If it is found—as it often is—that the soil thrown back from the border into the trench more than fills it, and that it hampers the workman at his work, have it wheeled away, as ultimately all this shifted soil will have to be cleared away. Assuming now that the whole of the soil has been cleared away from the roots of the Vines to within 3 feet of their stems, the next thing to do is to collect the liberated roots carefully together and turn them back on to the top of the border at the base of the Vines, placing a wet mat over them and a fairly heavy board on the top of that to keep them in position until wanted for replanting.

The Bottom of the Border.—

Having cleared the whole of the soil away from the part excavated, an opportunity will be given to examine the drainage. If the border is found to rest on a subsoil of gravel or any other material sufficiently porous to admit of the free passage of water, no better bottom is needed; but should it be resting on clay or some other substance equally impervious to the passage of water, the bottom must be concreted and drainage secured by the insertion of rows of 3-inch drain-pipes at distances apart of 4 feet, having sufficient fall and an effective outlet, filling in between the pipes (and deep enough to cover them) with broken bricks, stones and potsherds. Should it be found in clearing away the soil from the border that some of the Vine roots have penetrated into the subsoil, rather than try to trace them to their source and lift them for replanting it will be better to cut them off, as such roots are of practically no value to the Vine. We have now finished what may be termed the pulling down or destructive part of the work of renovating old Vines, and will now proceed to the more congenial part of building up new material which is to give new life and greater fertility to the Vines.

The Soil.—It is considered by some gardeners to be an advantage to cut and stack the turf before it is wanted for use. My experience of making Vine borders goes to show that there is no advantage attending this practice.

The first thing to do before preparing the new soil is to find out about how much will be required to fill up the new border. The planter must bear in mind that little more than half the space of the border which has been cleared of soil will be available for filling up for the present replanting of the Vines, the other portion being reserved for another addition of fresh soil to the roots in two years' time. As the success of the Vines for so many years will depend on the quantity of the soil in which their roots are planted, no expense or trouble should be spared in obtaining the right sort. The best is that obtained from an old meadow pasture, of heavy rather than a light

texture, with a fair depth of loam underneath, and resting on sandstone, limestone, or even gravel. The grass must first be cut off as close as possible, and the turf may be cut into any lengths and widths desirable, but they must not be cut of greater depth than 5 inches. It is only at this depth that masses of grass roots, or fibres, are found in the turves, and which add so much value to Vine soil. The turf should be chopped up with a sharp spade into pieces the size of the fourth of a brick. To each cartload of such turf add two barrow-loads of old broken bricks, reducing them to the size of a hen's egg,

of course, run the whole length of the border. This will give a space of close on 3 feet to be filled with new soil for the Vine roots to root into, and still leave space behind the turf wall to be filled up with new soil for the further encouragement of the Vine's growth in two years' time. In commencing to fill the space between the turf wall and the roots of the Vines with the new soil, the largest and coarsest of the lumps of turves should be selected and placed at the bottom on the drainage to the depth of 5 inches, ramming them down firmly. Before proceeding to add any more soil to the new border, we must now

examine the roots placed under the mat as directed. All it will be found necessary to do will be to cut back the jagged ends of the shortened roots with a sharp knife, taking care that the cut is a slanting one and the surface of the cut facing upwards. From this cut, facing upwards, roots will be formed with a tendency to grow upwards, forming valuable surface roots; on the other hand, if the end of the root is cut with the face of the cut part facing downwards, the new roots formed would have a decided tendency to strike down to the bottom of the border, and probably to the subsoil.

Planting.—In the first place, put a layer of the new soil 4 inches deep over the rough, turfy soil already at the bottom of the border, pressing it down firmly. On this place the bottom layer of roots, packing the soil over and round them firmly with the hands. Add another layer of soil of the same depth and a layer of roots as before. The last layer of roots should be 6 inches below the surface of the border when it is finished. It will be observed that the soil placed over each layer of roots should be firmly pressed down, as Vines succeed so much better in firm soil than in that which is loose and light. The soil at planting-time should be on the dry rather than the wet side.

We have now finished replanting the roots of the Vines. It only remains for the space of the old border left vacant behind the wall of turf to be filled with fresh leaves. Beech or Oak leaves for

preference, and be trodden down hard. New summer roots will find their way into the leaves, with the result that considerable added strength will be given to the restoration of the Vines. These leaves should be taken out the following winter, cutting away any roots there may be back to the face of the wall of turf, and filling again with leaves as before. The second winter the leaves must be taken away and the roots treated as before, the space filled this time with soil and made to form part of the new permanent border. I have been presuming that the Vines under treatment are growing in a double border (inside and out) and that the inside only has been treated.

THE BALEARIC SANDWORT (*ARENARIA BALEARICA*) FORMING A FLORAL CASCADE IN THE ROCK GARDEN.

and adding the small stuff and the dust which comes from them (the function of this material is to keep the border sweet, porous and well aerated), one barrow-load of old mortar or plaster rubble, a small barrow-load of quicklime, 20 lb. of half-inch bones and the same of bone-dust, and half a bushel of soot or of wood-ashes. Mix the whole well together by turning over several times, when it will be ready to plant the Vine roots in.

The first thing to do in starting on the new border is to build a wall of turf about a foot wide and as high as the surface of the old border, and at a distance from the stems of 6 feet (it will,

The outside part will have to be served in the same way as the inner one, and in the case of single borders, either inside or outside, the treatment will have to be the same.

The border should receive a good soaking of clear water to settle the soil about the roots as soon as the planting is finished, afterwards covering the border to the depth of 7 inches with leaves to keep it fairly dry and safe from the effect of severe frosts. The leaves should be removed the first week in May, and the border left exposed for a fortnight to dry and sweeten its surface, when it may receive a good soaking of weak manure-water, afterwards adding a mulching of fresh horse-manure and loam in equal quantities, with a light sprinkling of bone-dust. This mulching should be 3 inches deep and pressed firmly to the border, covering it to the same depth with half-decayed litter to prevent too rapid evaporation. As a result of this treatment it will be found that by midsummer, or soon after, the new soil and mulch will be densely permeated with new feeding roots, and the Vines correspondingly strengthened.

My remarks so far have applied to root culture alone, which, after all, is the mainspring to all good culture, as, unless a plant or a tree possesses abundance of healthy, strong roots, successful results are impossible. I will only say this much in reference to the culture of the Vine itself under glass—that the cultivator must bear in mind the rough ordeal the roots of the Vines have gone through. The Vines must not be forced prematurely into growth, but allowed to break naturally through sun-heat in spring, the object being to secure as strong a break of shoots as possible. The Vines should only be allowed to carry a very light crop the first year after lifting; afterwards they may carry full crops. X. Y. Z.

BERRIED SHRUBS FOR THE ROCK GARDEN.

DURING the autumn and winter months, when rock garden flowers are by no means plentiful, the dwarf Cotoneasters, with their scarlet or red berries, and, in some instances, evergreen foliage, are interesting and beautiful. There are several species well adapted for planting at the summits of good-sized boulders, over which their neat, close-growing branches can trail; or, if preferred, such as *C. horizontalis* can be planted at the foot of a large rock, which, as it grows, it will hug so closely as to almost appear to be part of the rock itself. This is a deciduous species, but in autumn and winter its branches are bespangled with scarlet berries. *C. microphylla*, as its name implies, has very small leaves. It forms a neat little shrub, and is evergreen. It has red berries, and is perhaps the best of the older species for the rock garden. *C. rotundifolia* is deciduous or sub-evergreen, the leaves being nearly round and dark green in colour.

It has red berries, which are usually produced in abundance. All three are natives of the Himalayas, and are not difficult to grow. *C. adpressa* was introduced to this country from China some years ago, and promises to be a very useful shrub for the rock garden. It is of very dwarf habit and deciduous, but before they fall the leaves turn a beautiful orange colour. It has small pink flowers, which are succeeded by red berries. *C. humifusa* or *C. Dammeri* only grows a few inches high, and is admirably adapted for trailing down the face of a projecting rock. It is evergreen, the foliage taking on a fine tint in autumn, which harmonises well with its scarlet berries. All these Cotoneasters like good loamy soil, and *C. humifusa* appreciates a little peat mixed with the loam. They should be given a fairly deep root run; a foot is not too much for *C. horizontalis*, *C. rotundifolia* and *C. microphylla*. All can be successfully planted

THE MARSH MARIGOLDS.

IT would be difficult to find a more pleasing British bog plant than the common Marsh Marigold or Kingcup, *Caltha palustris*. Its brilliant golden blooms, so neatly set off with a foil of delicate green foliage, transform our swamps into beautiful pictures during the latter part of April and the early days of May. In the Southampton district we have vivid recollections of acres of marshland transformed almost into a carpet of gold with the blooms of this plant. Happily, in our gardens we are broad-minded enough to make use of this wilding by the margins of ponds or lakes, where vegetation of many kinds can be allowed to follow its own sweet will and produce its floral tribute unspoiled by too severe restriction.

A WATERSIDE SCENE IN THE GARDENS AT LOCKINGE—MARSH MARIGOLDS IN THE FOREGROUND.

early in April, but it is advisable to obtain plants that have been established in pots. S. X.

THE BALEARIC SANDWORT.

THERE are few more easily grown plants in the rock garden than the dainty little Sandwort that has the rather unwieldy name of *Arenaria balearica*. It loves a shady and, in summer, a rather moist situation, where it will quickly establish itself and form a perfect carpet of vivid green. When in May this verdure is closely studded with the tiny white, star-like blossoms, the plant never fails to elicit praise from even the veriest tyro. In the illustration on page 544 it will be seen forming a sort of floral cascade over some sandstone boulders, the effect thus created being a particularly happy one. Although it prefers shade and moisture during hot weather, this plant is so accommodating that it will give a good account of itself in almost any situation. It is easily propagated by division, preferably during moist weather in spring

In addition to the ordinary Marsh Marigold, there are two varieties with double flowers, viz., *C. palustris flore pleno* and *C. p. monstrosa plena*. Both are useful for the waterside or bog garden, and the accompanying illustration shows a few good plants of the former in the famous gardens at Lockinge. A comparatively new addition to the genus, and a giant in stature, is *C. polypetala*, a very noble plant that ought to be found on the margins of every garden pond in the country. It attains a height of 2 feet, and its large yellow flowers are produced on stout, robust stems. Individual leaves often measure 1 foot across, hence when not in flower it is quite an attractive plant. These Marsh Marigolds are by no means difficult to grow, and can be planted at almost any time during the winter, though many prefer early spring. They all need moist soil, and are best planted in fairly large pieces, preferably by the side of a stream or pool, as shown in the illustration.

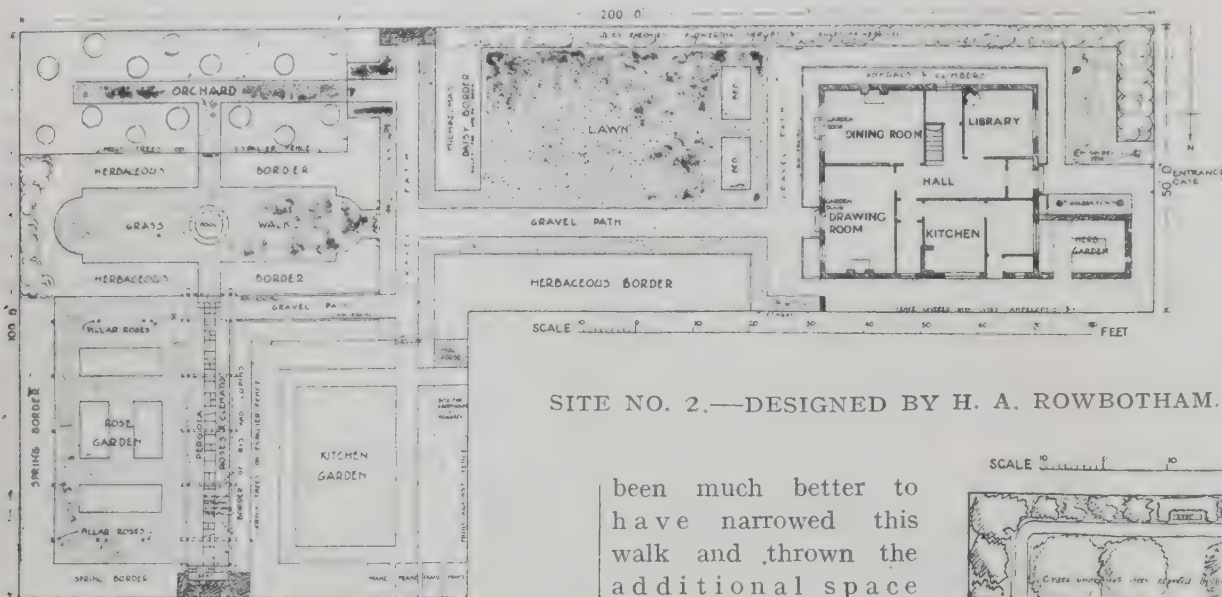

THE LITTLE GARDEN.

FURTHER PRIZE DESIGNS IN OUR COMPETITION.

WE now reproduce a further series of designs which secured prizes in our recent competition. Mr. H. A. Rowbotham won a book prize for Site No. 2. A good point about his scheme is that he has kept steadily in mind the views

(not reproduced), to which a book prize was also awarded. In his No. 3 design we notice the common failing of a pergola which bears no very definite relation to anything, though it has the subsidiary advantage of screening the little alpine garden from the Rose garden south of the dining-room. Something may be said in criticism of providing a gravel walk 10 feet wide and nearly 100 feet in length. It gives a rather cold and bare appearance, and takes an amount of maintenance which we should grudge. It would have

In discussing the making of the little garden, *Country Life* lays down six outstanding points which need to be borne steadily in mind. "In planning it is important (1) to ensure that every part of the garden shall bear a definite relation to the house which it serves. (2) That the design shall be essentially simple, *i.e.*, that the space shall not be frittered away by multiplied features; and (3) that the lines of these parts shall be so laid down that the whole shall achieve a definite shapeliness. The three points in planting are subordinate to the fact that the owner of a little garden can rarely devote either much money or considerable labour to its tending. He, nevertheless, should seek to secure (1) a sufficient rotation of flowers to ensure gaiety in the garden during spring and summer and early autumn; (2) as rich a pleasure in colour and scent as may be contrived with small expenditure; and (3) some practical return for his labour in vegetables and fruit. Many blunders would be avoided if it were generally appreciated that the whole garden scheme should be considered from the first in its relation to the house."

SITE NO. 2.—DESIGNED BY H. A. ROWBOTHAM.

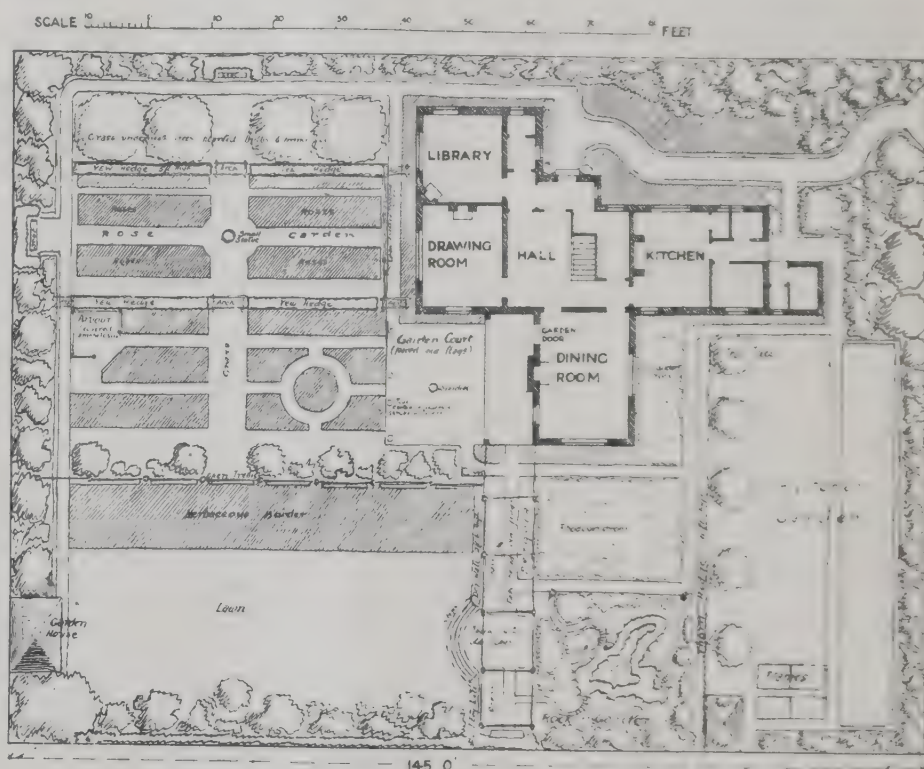

from the windows of the two principal rooms, but its defect is in the rather too ample spaces he has given to borders, &c. This garden would certainly take a lot of work to keep it up. The kitchen garden is well screened from the Rose garden, not only by the pergola, but also by espalier fruit trees, which are further used to form a boundary on its south side. It is not so clear that the espalier fence which borders the south-east corner of the site is so well placed, because the standard trees would keep the south sun from the fruit. The general criticism of the design is that it is rather too much cut up, and would in practice have a somewhat spotty effect.

Mr. Ernest Biggs shows some good ideas in his scheme for Site No. 3, which secured a book prize, but there seems to be no justification for the shapeless outline given to the entrance path. The draughtsmanship suggests that this competitor is more familiar with the practical side of gardening, and probably the scheme, if worked out, would look better than the drawing suggests. The pergola is well placed, because it joins up directly with the house verandah and leads to the rock garden, which it cuts off from the herbaceous garden to the west. It is doubtful whether a bank of Rhododendrons is a very interesting feature immediately outside the south window of the dining-room.

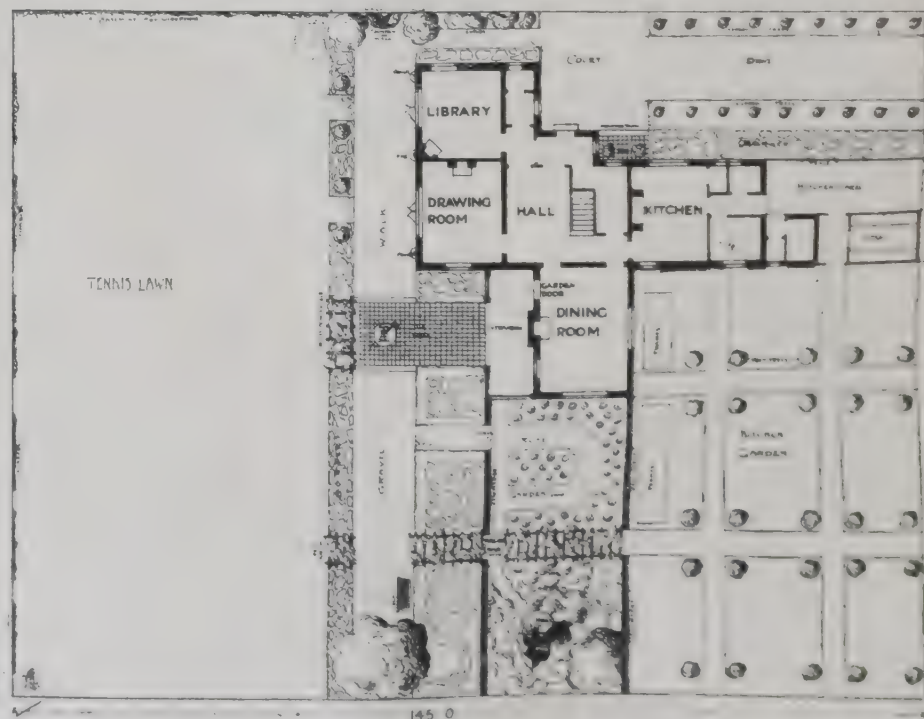

The last design we shall consider and reproduce is also for Site No. 3, for which Mr. Thornton Sharp received a book prize. It is in strong contrast to the treatment of the last design, which showed the minimum amount of plain lawn, whereas in Mr. Sharp's case he evidently thought that the demands of lawn tennis were paramount. He has succeeded in providing a lawn 50 feet wide, which is 10 feet narrower than the ideal, but the maximum that the site would allow. This competitor is evidently somewhat wedded to rustic features, which are not, however, used so extensively here as in his design for Site No. 4

been much better to have narrowed this walk and thrown the additional space into the borders, which would look distinctly meagre in so narrow a width as 4 feet. In the case of a design like this, where the claims of the tennis lawn greatly reduce the space available for other flowers, the proper policy to pursue is to mass the colour effect in a generous fashion, and that cannot be done with a 4-foot border. The kitchen garden is well arranged, and divided from the private garden by a Yew hedge, while the garden shed helps to mask the kitchen yard.

Although many others among the drawings to which book prizes are awarded showed a considerable grasp of the problems of design, they do not show any features which are not represented in the schemes illustrated in this and our last three issues. Enough plans, however, have now been reproduced to mark the variety and skill which the competition has evoked, and we are satisfied that our readers will have derived both pleasure and benefit from the study of the designs.

SITE NO. 3.—DESIGNED BY ERNEST BIGGS.

SITE NO. 3.—DESIGNED BY THORNTON SHARP.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Succession Peach Trees.—The pruning, washing and tying of these trees should be accomplished with as little delay as possible, so that by the end of the year all such work may be finished. Let the shoots be well thinned out before the trees are untied, so that the operator can see at once which shoots to remove. The aim should be to remove a number of old, unfruitful shoots each season, so that space may be available for tying in young fruiting wood. In cases where the soil has become exhausted, it is necessary to remove as much of it as possible without injury to the roots, and replace it with good, rich loam, to which a quantity of old lime rubble and crushed bones has been added. If the trees are young and the borders in good condition, the removal of an inch of the surface soil will be sufficient. See that the soil does not become too dry, or bud-dropping may result in the spring.

Tomatoes.—Fruiting plants must be very carefully watered during the winter months. A night temperature of 60° is quite high enough in mild weather, and this should be allowed to drop to 55° if cold weather sets in. Keep the atmosphere on the dry side, and remove side shoots as they appear. Succession plants which are intended to produce supplies in January may be given some stimulant twice weekly, and the flowers should be artificially pollinated as they become open. Air should be admitted night and day until a crop has been secured, after which the temperature may be increased, if necessary, to keep up a regular supply.

The Flower Garden.

Summer Bedding Plants which have been rooted in frames should be freely ventilated while the weather is mild. The tops of the most forward plants may be pinched out in order to keep them stocky.

Ranunculus.—The present month is a suitable time to make plantations of Ranunculus, although planting is frequently put off until the early months of the year. By so doing, however, one runs the risk of bad weather, and the operation may have to be put off too long, the vigour of the plants being reduced in consequence. The soil should be deeply dug and enriched with a dressing of decayed horse-manure. Plant in rows 9 inches apart, and cover with 2 inches of fine soil; or they may be planted in clumps on a sunny border which is set apart for spring-flowering plants.

Climbing Plants on Walls or Pillars.—Many of these, having become entangled, should now be liberated and trained in their proper quarters. Clematis will require careful attention in order to keep the shoots from injury. Cut away all superfluous growths, and train the remainder carefully to the wires. It is advisable to retain a good portion of the young wood in case the shoots may be thinned by sharp frost.

Lily of the Valley.—November is a good month to plant roots of Lily of the Valley. The ground should be well prepared by digging in a good quantity of decayed manure and sharp sand. A border facing north or east will suit them well. The crowns should be planted in rows 1 foot apart, and covered in such a manner as to allow the points to be just showing through the ground. A covering of fine leaf-soil may be placed over the border to the depth of 1 inch.

Plants Under Glass.

Arum Lilies.—If blooms are desired for Christmas decoration, some of the most forward plants should be placed in heat at once. A newly started vinery will suit them well. With regard to heat and moisture, water freely with liquid manure, and keep the plants well exposed to the light. For succession plants a frost-proof house is all that is necessary at present.

Eucharis grandiflora.—Plants which have been resting during the autumn may now be placed in a temperature of 70° with a view to producing flowers about the end of the year. These plants require a good supply of moisture to the roots, and, when the flower-spikes begin to push up, liquid manure should be freely given. If insects

are present on the plants, the foliage should be carefully sponged before the plants are placed in heat.

Begonia Gloire de Lorraine.—The earliest batch of these plants are now in full bloom, and will benefit by a slight drop in the temperature; 65° at night will be quite sufficient after the flowers have developed. Keep the atmosphere moderately dry, and open the ventilators during the early part of the day. Successional plants should be well supplied with atmospheric moisture and frequently watered with artificial manure.

The Hardy Fruit Garden.

Planting Bush Fruit Trees.—There is no time like the present for making new plantations of Gooseberry or Currant trees. In all cases the ground should be trenched and a good dressing of decayed manure given. If the ground is of a heavy nature, a quantity of wood ashes or old lime rubble may be mixed with it as the work proceeds. A space of 5 feet should be allowed between the plants, as this will permit them to grow for several seasons without being overcrowded. The planting of all kinds of fruit trees should be pushed forward while the weather is mild and dry. No work in this department is of such importance at present.

The Kitchen Garden.

Mushrooms.—If horse-manure is available, collect and prepare it for making up new beds, from which supplies may be expected about the end of the year. The material should be placed in an open shed and turned every second day, until sufficient has been collected to make up the bed. Make this quite firm by ramming, and spawn when the temperature of the bed decreases to 80°. Keep the atmosphere moist by damping the walls and floor, but avoid frequent watering of the bed. Avoid fire-heat, as this has a drying influence on the atmosphere; 50° to 55° is quite high enough.

Cauliflowers in Pits.—These plants should be freely ventilated during mild weather. Finish potting as quickly as possible, so that the plants may become established before winter sets in.

Lettuce in cold pits should be left uncovered as late in the season as possible, in order to keep the plants hardy. Keep the soil moved between the plants, and dust frequently with lime to keep slugs in check. Lettuce seeds may still be sown in a cold pit to produce plants for the spring. Maximum, Stanstead Park and Hardy White Cos are good varieties for this purpose.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Winter Spinach.—This important winter vegetable should be closely examined, and all weeds and decaying leaves at once removed; the latter are very harmful. Should the plants seem too close together, it will be as well to draw out a few, disturbing the soil as little as possible.

Potatoes.—Where these are forced early, the sets should now be selected and placed in shallow boxes with a view to starting them into growth. Some fine soil ought to be worked in among the sets, and have the boxes placed where there is a good light to encourage sturdy growth. Midlothian Early and Sharpe's Victor are excellent varieties for this early work.

Autumn-Sown Onions.—In many districts the transplanting of these may be done now; indeed, where this is possible, better results may be had from those planted now, as it checks too rapid growth. On the other hand, where the soil is heavy, and consequently cold and wet, it is much better to defer transplanting till the early spring.

The Flower Garden.

Roses.—The planting season is now here, and although planting may not have to be done to any extent, there are sure to be blanks to be filled up, or, it may be, the trunk of an old tree to be furnished. In this connection much can be done to brighten odd corners in the flower garden by planting here and there an occasional climbing Rose. Planting in such places should, as

far as possible, be carried out before the end of the year.

Salvia patens.—This lovely blue-flowered plant has been very fine this autumn, and was in bloom till well into October. When the growth has been cut down by frost, the tubers should be lifted, placed in boxes, and given the protection of at least a cold frame. In many districts the plant is allowed to remain outside during the winter, but at best this is rather risky. Unlike many other tubers, it must not be kept very dry, as, owing to the lateness of the growth, the roots are inclined to shrivel.

Pampas Grass.—Very few plants produce such a fine effect at this season of the year as the Pampas Grass, to say nothing of its usefulness in making up large vases for house decoration. These plants must now be protected from frost during the winter. Many fine specimens are lost annually through not observing this precaution. For these and similar plants there is possibly nothing better than sifted ashes for protection.

Rock Garden.—Many small alpine and rock plants of doubtful hardiness must be closely examined during cold and foggy weather. In some instances it may be necessary to transfer the choicest of these to the alpine frame. But as damping is most to be feared, a handful of small granite chips placed carefully round the plants may serve to bring them safely through the winter. Remove all decaying leaves and other rubbish which tends to create dampness.

Plants Under Glass.

Camellias.—Attend carefully to the watering of these hard-wooded plants at this season, whether grown in pots or planted out, as, if allowed to become dry at this stage, serious damage may result from buds dropping in the spring. Plants well set with buds may have frequent applications of liquid manure, and where buds are rather numerous these may be reduced gradually.

Ferns.—Among the greater number of these, active growth will have ceased for the season; therefore the greatest care must be exercised in watering. Although these must never be allowed to become dust dry, the supply of water to the roots should be reduced, to enable the plants to have a complete rest. This, of course, only applies to the deciduous varieties.

Roses.—Those growing on pillars or on the roof should now be pruned, and though cleanliness is essential to the well-being of all indoor plants, it is especially so with Roses, owing to the fact that they are mostly grown against walls, and therefore more difficult to keep clean. Before tying them up, have the wall and woodwork thoroughly washed down. As soon as they have started into growth, ventilating must be carefully attended to, as draughts will most assuredly bring about mildew. As a preventive it will be a good plan to put flowers of sulphur on the hot-water pipes.

The Hardy Fruit Garden.

Pruning Gooseberries.—Where large breadths of these are grown, the pruning is often very protracted work. A start, however, should be made at once, especially on wet and heavy soils. These, when the work is left until later, become very wet and sticky and make the task much more unpleasant. In this early pruning, allowance must always be made for depredations by birds by retaining a few extra shoots; that is, of course, if means cannot be adopted to protect them. Whatever method of pruning is followed, the centre of the bushes must in all cases be well thinned out, or, as I pointed out on a former occasion, the centre shoot may be trained to a stake.

Fruit Under Glass.

Late Grapes.—Owing to the dull and foggy weather usually experienced at this season of the year, special care will be necessary in the management of the late varieties of Grapes still hanging. Lady Downe's, with its thick skin, will be fairly safe for another month yet; but such varieties as Alicante and Lady Hutt will, owing to the size and thickness of the bunches, be more liable to be affected by dampness. An equal temperature of about 50° should be maintained and the house freely ventilated on fine days.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N. B.

CULTIVATION AND COLLECTION OF MEDICINAL PLANTS IN ENGLAND.

[The following has been recently published as Leaflet No. 288 by the Board of Agriculture.]

MEDICINAL herbs have been cultivated in this country for centuries, and in the Middle Ages were grown in kitchen gardens attached to monastic establishments and the mansions of noblemen. At the present day *materia medica* (or drug) farms exist at Mitcham, Carshalton, Hitchin, Ampthill, Long Melford, Steppingley, Market Deeping and Wisbech, but for many years the main source of British drugs has been mid-Europe, particularly Germany and Austria-Hungary.

During recent years the acreage devoted to drug cultivation in Britain has been more and more restricted by competition with wild foreign products, and the result has been a slow but sure ousting of British-grown drugs from the market. The advent of a European war has completely changed the situation, and an effort on the part of growers and drug merchants may largely secure for England the collection and cultivation for the future of medicinal plants which can for the present no longer be imported from Central Europe. Supplies of drugs, especially of Belladonna leaves and root, are much in demand, but in the case of other Continental drugs grown in England the shortage is not so serious.

The price of Belladonna has risen seriously (more than 100 per cent.) since the outbreak of war, and as it takes at least two years to grow this drug in quantity, the drug grown next year is likely to realise high prices. This applies in lesser degree to Chamomile, Dill, Dandelion and Valerian. The prices of Colchicum, Digitalis, Fennel, Henbane, Stramonium and "botanical herbs" must also be considerably affected.

The limited outlet for most drugs makes overloading the market a comparatively easy matter, and any grower who proposes to devote attention to the cultivation of medicinal plants should give the matter careful consideration before embarking on it to any serious extent. For a number of growers, however, who can successfully raise good crops, handsome profits should be made in the near future.

Co-operation.—The most important drug industry—Cinchona bark production—has witnessed quite recently the fruits of co-operation between producer and manufacturer in restricting the output within reasonable limits. So far, consumers appear to be unaffected, while all other handlers of bark and quinine, other than speculators, are in a decidedly better position.

Some arrangement might perhaps be made to ensure British drug-growers a fair return for their efforts. Co-operation between growers and wholesale druggists would probably prove effective.

Soil and Manuring.—Soil in good condition for ordinary farm crops is suitable for growing most medicinal plants. In general, care should be taken to keep down weeds and ensure a good tilth. A medium dressing of farmyard manure is usually advantageous, although not actually necessary.

Drying of Crops.—The drying of medicinal herbs is a matter of great importance, and regular growers have proper drying plant, heated arti-

ficially, so that quantities of the drugs can be dried quickly and thoroughly in a current of warm air. Facilities for drying purposes are necessary to the grower of medicinal herbs. Glass houses could readily be converted into drying sheds, especially if heated by pipes. Drying could be done in half shade in fine summer weather by spreading thin layers of the leaves on sheets in the open, or on racks or shelves in a freely ventilated shed, turning frequently until quite dry. The leaves or flowers must be kept under cover at night or during rain. "Even colour" is best retained by quick drying, and the brighter the colour the more saleable the product. Those who intend to market dry leaves or flowers could gather and dry in small portions, which are more manageable. Roots present less difficulty in washing and drying.

The most important British drugs are dealt with briefly here, while a number of others are also mentioned, though their supply is more or less restricted.

The South of England is especially suited to drug-growing, and is further favoured in being close to the principal consuming market.

The greatest difficulty to be encountered by the grower will be to obtain sufficient seeds or dormant plants to start growing medicinal herbs.

ACONITE (ACONITUM NAPELLUS, L.).

The chief collecting centres for foreign Aconite root are the Swiss Alps, Salzburg, North Tyrol and Vorarlberg. Swiss supplies (which have come *via* Germany) may be cut off as well as the others. Supplies of Japanese Aconite root are plentiful, and Spanish root is also coming into the market, so that the demand for English Aconite will probably be restricted. The price of the Continental root is about 50s. per cwt., and Japanese (usually ascribed to A. Fischeri, Reichb.) about 35s. per cwt., while English is ordinarily worth 2s. per lb. Cultivation of Aconite has not paid in recent years, even with cultivated root four times the price of wild. Leaves are of little importance.

Cultivation.—The official Aconite (*Aconitum Napellus*, L.) grows wild in some shady places in the West of England and in South Wales. It prefers a soil slightly retentive of moisture, and among the drug farms the moist loam of Ampthill or the dark soil at Market Deeping proved most suited to Aconite cultivation.

Beds for growing Aconite are all the better for being shaded. The soil should be well dug, and pulverised by early winter frosts. The digging in of rotted leaves or stable manure is advantageous.

Aconite can be raised from seed, but it takes two or three years to flower. It is almost invariably propagated from the smaller (daughter) roots which develop at the sides of old roots. The underground portions of the plants are dug up in the autumn, after the stem has died down, and sorted over, the plumper roots being reserved for washing, splitting and drying to form the Aconite root of commerce.

Replanting is usually done in December or January, the young roots being planted about a foot apart each way. The young shoots appear above ground in February. Although the plants are perennial, each root lasts only one year. The autumn-dug daughter root crowned with undeveloped buds is official in the British Pharmacopœia, but German root is derived from plants gathered in flower. Aconite would grow luxuriantly in a moist open wood, and would yield returns

with little further trouble than weeding, digging up and drying. A great disadvantage of growing Aconite from seed is the uncertainty as to correctness of the species, an important point as regards medicinal activity. There are some sixty species.

BELLADONNA (ATROPA BELLADONNA, L.).

Prospects.—The bulk of the world's supply of Belladonna is derived from wild plants growing in quantity on waste, stony places in Southern Europe. The industry is an important one in Croatia and Slavonia (South Hungary), some fifty exporters being engaged in buying the root and leaves from collectors and exporting the drug chiefly to Würtemberg. The largest exporter in Slavonia sent out 29,880 lb. of dry Belladonna root in 1908.

Continued shortage will almost certainly exist during the next few years. If seeds are sown in October, a small crop of leaves may be obtained in the following year if plants grow strongly. High prices will probably continue until the root is dug three or four years hence. It is usually difficult to obtain more than £10 per acre for a crop of Belladonna, but those who can contract to deliver Belladonna next year should obtain more than this for the sparse first year's cutting.

Cultivation.—Belladonna is grown from seed, and an initial difficulty will be to obtain supplies of fresh fruits or seeds. The plant grows wild in the Southern Counties of England, especially near old ruins, but it has become much rarer of late years. The fruits ripen from August to October, and those who know the haunts of the plant might profitably gather fruits for sale. The seeds taken from the berries are washed in a sieve and dried.

Belladonna grows on most soils, but is partial to a chalky substratum. The seeds germinate slowly, and some autumn sowing is necessary, but sowing may also be done in spring. The seeds are drilled in rows 3 feet apart, using 2 lb. to 3 lb. of seed to the acre. A reserve of plants is also grown in seed-beds to fill in gaps due to dormant seeds and winter's losses. The seedlings are liable to injury by late frosts, and a light top-dressing of farmyard manure serves to preserve young shoots from injury during sudden and dangerous changes in temperature. Healthy young plants soon become re-established when transplanted, but require watering if the weather is dry at the time of transplanting. Great care must be taken to keep the crop clean in spring, or the seedlings may be choked by weeds.

The plants may be left 18 inches apart the first year, and by September the single stem will be 1½ feet to 2½ feet high. A gathering of leaves may then be made if the plants are strong. "leaves" meaning the broken-off tops of the plant. The coarser stems are left on the plant, and discoloured portions are rejected. Women are employed for gathering. Before the approach of winter, plants should be thinned to 2½ feet to 3 feet apart, or overcrowding will result in the second year, in which the plants will bear one or two strong stems.

The English crop is cut with sickles in the second year while flowering in June, and is usually carted straight to the factory for extract making (*i.e.*, before it has time to "heat"). The leaves (tops) lose four-fifths of their weight on drying, an operation attended with difficulty. Growers who intend to have their crop worked up into extract must arrange for delivery at the mills on the day it is cut, because heated material is useless for

extracting. With modern motor traction it should be possible to deliver twenty miles away very quickly.

The average crop of fresh herb in the second and third years is 5 tons to 6 tons per acre. A second crop is obtained in September in good seasons. The plant is dug or ploughed up during autumn in the fourth year, and the root is collected, washed and sliced to accelerate drying. In time of great scarcity it would probably pay to dig up root in the third year. Three parts of fresh root yield a little over one part of dry root. The greatest loss of plants is in wet winters. On the lighter soils there is less danger from winter loss, but the plants are more liable to damage from drought in summer on such soils.

(To be continued.)

BOOKS.

National Dahlia Society's Supplement.*—

The annual Supplement and Conference Report of this society is before us, and constitutes a useful addition to others which have preceded it. Quite fittingly in a prefatory note reference is made to the loss the society has sustained by the death of its president, Mr. George Gordon, V.M.H., who did so much for the advancement of the Dahlia as a garden flower. The tribute is accompanied by an excellent photograph of Mr. Gordon. A special value attaches to the present supplement, in that it deals with the extensive trials conducted during the year 1913 at Duffryn, near Cardiff; and Mr. Cory's observations thereon, which extend to all sections of the flower, will doubtless be perused with interest. The trials in question are the largest ever conducted in a private garden, and it should be remembered that one of its chief objects was to test the decorative or garden value of the flower. To this end Continental and home growers were invited to contribute varieties they deemed valuable for the purpose, the result being that between 7,000 and 8,000 plants in nearly one thousand distinct varieties were received. The report deals in detail with the numbers received in each section and those gaining commendation; hence its value. For example, 150 Collarette varieties were received and only twenty-three honoured. Complete lists of all so honoured follow in their sections, with colour and height. Mr. H. Shoesmith contributes a paper on "The Dahlia of To-day," which is well worth perusing. Included are photographs of Mr. Reginald Cory (in whose garden at Duffryn the 1913 trials were conducted) and of Mr. Joseph Cheal, chairman of committee.

Saxifrages.†—This handy volume, which, with appendix and index, extends to nearly one hundred and fifty pages, treats of one of the most important and, for the most part, fascinating families of hardy plants, one which, so far as the rock gardener and alpine lover is concerned, is as a treasure-house from which rich stores may be taken at will. The book, too, in view of the promised conference on the genus in 1915, comes at an opportune moment, though at any time it would have been welcome. It is, so far as we remember, the first of its kind in the English language, and now that it is an accomplished fact it will be welcomed

as "guide, counsellor and friend" by the thousands who now cultivate the many species and varieties the genus contains for the pleasure they afford. Bereft of its Saxifrages, the rock garden or alpine house would be poor indeed; and even these do not exhaust the resources of this valuable race of hardy plants. Others there are just as well suited as edgings to shrubbery borders, to woodland places and the bog garden; and it is these all-embracing characteristics, with simple cultural requirements for the most part, which places the genus upon the topmost rung of Popularity's ladder. Apart from an intellectual chapter on the "Saxifrages of the Pyrenees," by Dr. John H. Salter, and "Saxifrages in the Rock Garden," by Mr. R. A. Malby, the book resolves itself into a monograph of the genus, treating of the species in their several groups, of which fifteen, with an illustrated key, are given in its opening pages. In these chapters we have the essence and value of the volume backed by the authoritative experiences of the author at Kew, where for so many years he has cultivated an almost unique collection of these plants, and so well. Emanating, as it were, from such a source, the amateur will be relieved to learn that the descriptions are devoid of technicalities and couched in the simplest terms, and will be readily grasped by all. In an opening paragraph at the head of the more important groups and interspersed with the descriptions of some of the species are to be found concise cultural hints of some importance. Despite these facts, we should have preferred to see—and are of opinion that a greater service would have been rendered to the Saxifrage-loving public had there been—brief chapters devoted to "Cultivation and Propagation," to "Uses and Adaptabilities," to selections for "Grouping," "Colonising" or "Crevice Planting," and to other things. Chapters on such important matters would have tended to make a valuable work *invaluable* to the amateur, who, hungry and thirsting for such knowledge, is, after all, the only one to cater for, the specialist knowing these things by heart. In all, the book, according to the index, embraces upwards of three hundred species, varieties and hybrids, a number which, while demonstrating the importance and extent of the genus, is, even then, by no means exhaustive. But it gives of the best and, as the author points out in a prefatory note, is intended "to help the garden lover to become acquainted with the most important members of the family, so that he may be able to choose the best varieties, and, having chosen, to grow them successfully."

A few clerical errors, inseparable from a book when more than one writer contributes thereto, should be righted in future editions. At pages 101 and 128 appear "Haagei" and "Haagii"; at pages 103 and 129, "Obristii" and "Obristi"; at pages 108 and 123, "Dr. Ramsey" and "Dr. Ramsay"; and at pages 129 and 105 Sundermanni is rendered with one "n" and two "n's" in the final syllable. At page 22 "Guildford Seedling" is cited as the product of "S. muscoides var. atropurpurea," though the writer had it on the authority of the late Mr. Selfe-Leonard, in whose collection it originated, that it came as a "chance seedling from S. m. Rhei." "Faldon-side," again, at page 100, is cited as being of burseriana x retzioides parentage, whereas it occurred as a subsequent seedling from S. Boydii, as did S. B. alba and S. B. lutea, hence is only related to the above parentage in this connection. The parentage of S. bursiculata should have been

given as burseriana major x apiculata, its raiser's name "Jenkins," not "Jenkyns." These hybrid Saxifrages, with their known or presumed parentages arranged in a chapter apart, constitute a most interesting part of the book, an invaluable guide—if not quite infallible—to the student or worker in the same field, since, however large or extended this hybrid set might now appear to be, we lean to the view that the hybridist has only just commenced his work. The only thing we dissent from in the book is the author's recommendation (page 62) to "keep the rooted cuttings in their cutting pots over the winter," experience showing that much better results are obtained when the cuttings of these plants, in common with others, are potted off as soon as well rooted.

Some excellent illustrations in colour and monochrome are worthy of remark, and these, while a feature in themselves, serve to ornament a book of high importance to the lover of alpine flowers.

E. H. JENKINS.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

THE GREENHOUSE.

HEDYCHIMUM GARDNERIANUM NOT FLOWERING (C. G. O. B.).—We think that the probable cause of your Hedychiums failing to flower is that the rhizomes are not strong enough. This plant is as a rule far more satisfactory when planted out in a prepared bed in a sunny conservatory than it is when confined in pots, as in this way, especially if the shoots are crowded, it does not make growth sufficiently strong to flower. The plants at Kew referred to by you had been liberally treated in every way; that is to say, the shoots were limited in number, the pots large, ample stimulants had been given, and the plants derived a considerable amount of assistance from the warm yet stagnant water in which they were standing. We should advise you to remove the plants from the pans of water and gradually lessen the moisture at the roots till the stems drop away at the base, when the soil must be kept quite dry and safe from frost. Then early in the spring the plants should be repotted, using good-sized pots. A mixture of loam, well-decayed manure, with a little leaf-mould and sand, will suit them well. As the pots get full of roots, give liquid manure or some other stimulant freely. If you keep the soil dry, there is no need to knock the plants out of the pots. We have seen the Hedychium flowering freely out of doors in the neighbourhood of London, the plants being lifted during the winter

* "National Dahlia Society's Supplement." Published by the National Dahlia Society. Secretary, Mr. J. B. Riding, Chingford.

† "Saxifrages," by Walter Irving and Reginald A. Malby. London: Headley Brothers. Price 2s. 6d.

months and given the same treatment as Cannas. In the summer they were planted in an angle formed by two greenhouses, in which warm, snug spot they flowered freely. The soil was well dug and a liberal quantity of manure incorporated with it.

SCHIZANTHUS PLANTS FAILING (M. L. S.).—Your plants arrived in rather a bad condition, but we think they have been attacked at the roots by a fungus, probably a species of *Fusarium*, causing them to wilt in the same way as Tomatoes attacked by sleepy disease. It would be well to heat the soil thoroughly before sowing *Schizanthus* seed another year, so as to kill the spores of the fungus; and pots, &c., should also be sterilised.

TREATMENT OF HYDRANGEAS (M. G. B. C.).—You give us no idea of the size and condition of your Hydrangeas at the present time. At all events, the season is too far advanced for you to do anything before the winter. They should, if possible, be kept at that season in a position where they are just free from frost, but nothing more, otherwise they will not have the necessary period of rest. Then, early in the year, if the plants are large and bushy, any weak and overcrowded wood should be cut out, in order to throw the full energy of the plant into the stout terminal buds of the stronger shoots which can be depended upon to flower. If in your opinion the plants at that time need repotting, this should be done before the dormant buds burst, using for the purpose a good, fairly rich compost, such as two parts loam and the remaining portion made up of well-decayed manure, leaf-mould and sand. Where the plants do not need repotting, they should, from the time of starting into growth, be given occasional doses of liquid manure or some other stimulant. In order to turn the flowers blue, many preparations are used, with a lesser or greater measure of success. In some soils this is an easy matter, while in others it is difficult to obtain the desired shade. Two good preparations are sold for the purpose, namely, Azure, which is a speciality of Messrs. William Cutbush and Son of Highgate, and Cyanol, which comes from the Continent and can be obtained from horticultural sundriesmen. The presence of lime in the soil is very detrimental to the desired blue tint, hence the plants should never be given water that contains chalk. Rain-water alone should, if possible, be used. These preparations must never be applied while the soil is dry. The treatment, particulars of which are supplied with each preparation, should be commenced directly the plants are ready to start into growth.

INDOOR PLANTS IN BAD CONDITION (M. E. B.).—The portions of Palm leaf sent are very badly attacked by scale insects, which should have been destroyed when they were first seen, and not allowed to make such headway as they have done. It will be necessary to persevere in order to get rid of them, the best way being to sponge the leaves carefully on both sides with a strong solution of soft soap and warm water. This will tend to loosen the scale, which must then be removed with a pointed stick, taking great care not to scratch the surface of the leaf. This done, sponge over again with the solution; then rinse in clean water. The stems of the plant must also be treated in the same way, and a sharp look-out kept on the young leaves as they unfold. The fact that the other plants are smothered with green fly would indicate that they have been sadly neglected, for these pests should have been destroyed when first seen. They may be killed by fumigation, or more thoroughly by vaporising with nicotine if you have a place to isolate them when this is being done. Dipping in soft soap solution such as is advised for sponging the Palm will also destroy green fly. It is obvious that without an inspection of the plants and the conditions under which they are grown, it will be quite impossible for us to state the cause of the trouble and whether the potting soil is at fault. In any case, however, if you think the soil is unsuitable and decide to repot, it is too late to do so now. The better plan will be to wait till April. This last remark also applies to the *Aspidistra*, which should not be disturbed at this season of the year. Then, when the time comes round, the plant should be turned out of the pot and divided into as many pieces as there are crowns or tufts of leaves. If the basal portions of the long stems can be cut away without injury to the roots, it will enable you to work the tuft of leaves in the centre of the pot. With regard to *Aspidistras* behaving in this way, we find that there is a great deal of variation among individuals. We have had some plants for years, and while most of them are of good compact habit, one is no sooner potted than it makes tracks for the side of the pot and soon loses its symmetry. The name of the plant of which leaves are enclosed is *Anthericum lineare*, frequently known as *Phalangium lineare*.

FRUIT GARDEN.

PEACH BARRINGTON SPLITTING AND KERNELS DRYING (Barrington).—Late Peaches generally are liable to this defect, Barrington included. The cause is, we believe, to be found in the defective setting of the flowers. Lack of sufficient lime in the soil would, no doubt, help to this end. With such a heavy crop as your trees are carrying (and we presume it is the same in most years) the soil of the border becomes exhausted, not only of lime, but of most of its fertilising elements, and therefore it becomes necessary to top-dress the roots annually with the best new Peach soil. Before doing this, give copious and repeated waterings of manure-water to the borders as soon as the fruit is gathered. Attend carefully to fertilising the flowers with strong pollen from another variety, and do not crop too heavily.

PLUMS ATTACKED BY FUNGUS (Argyll).—The Plum is attacked by the fungus of brown rot called *Sclerotinia fructigena*. This fungus grows all through the

fruits, and fills them so full that they become mummies and remain on the tree the winter through. It also attacks the shoots. Both diseased shoots and mummy fruits should be removed and destroyed in the winter pruning, for it is from these sources that the fungus spreads to flowers and foliage in the spring and later to new shoots, &c. It would also be well to drench the tree with a solution of lb. of copper sulphate in twenty-five gallons of water during the winter, and just before the buds open, and again after the petals fall, to spray with Bordeaux mixture.

CHERRY TREE ON WALL NOT FRUITING (East Anglian).—Your better way will be to take up the Cherry tree, and if it is fairly young and in good health, replant in some other part of the garden, not necessarily against a wall, adding a liberal quantity of lime to the soil before planting. In place of the Cherry a young fan-trained Plum tree of the old Green Gage variety should be planted. You will find this will do well and give you in due time a better return than the Cherry. Trench the soil 2 feet deep where the tree is to be planted, and add a small barrow-load of turfy loam and a quart of bone-meal. The top roots of the tree when planted should not be buried more than 4 inches deep with soil. Tread the soil firmly before planting and afterwards. Plant when the soil is fairly dry.

MISCELLANEOUS.

TROUBLESOME WEED (Enquirer).—The weed is the Wood Horse-tail (*Equisetum sylvaticum*), one of the most pernicious weed pests of the garden, and certainly one of the most difficult to eradicate. So far as the path is concerned, that could be successfully dealt with by applying weed-killer at double strength during autumn and winter. If you gave two applications from October to February and another in spring when growth usually begins—all during moist or wet weather—we think you would quite eradicate it. For the garden soil the only possible way is to fork it out—the difficulties in the way of effecting a clearance being the deep-rooting character of the weed and the brittleness of its roots. As every atom of the latter is capable of giving rise to a new plant, the need for thoroughly cleaning out every particle of it is obvious.

WORMS IN MANURE (E. B. W.).—Worms and other insect life in manure may be destroyed by turning the manure and during the process mixing unslaked lime with it. The lime must be evenly distributed throughout the mass. The Apple weevil, the larvæ of the Codlin moth, can be checked by adopting preventive measures during the winter and early spring. During the winter the insects, of which the larvæ in the fruits is one stage in their life-history, are often found sheltering beneath rough bark. They may be destroyed by removing the rough bark and spraying the trees, when leafless, with a caustic wash. This may be made by taking 2lb. of caustic soda (98 per cent.) and dissolving it in a wooden vessel in three gallons of water. Then in another vessel dissolve half a pound of soft soap in a gallon of water, add five pints of paraffin, and stir until an emulsion is formed. Add the two mixtures together, make up to ten gallons with clear water, mix well and apply on a calm day. Afterwards the trees may be dressed with a lime wash. Any fruits containing weevils should be removed from the ground and destroyed, so that the weevils or caterpillars cannot change into mature moths. There is a very small choice of shrubs for planting in dense shade. A few of the best are common Holly, *Aucuba japonica*, Oval-leaved Privet, *Rhododendron ponticum*, *Berberis Aquifolium* and *Ruscus aculeatus*.

LAYING OUT A GARDEN (May Blossom).—It is not possible to introduce much originality into a narrow stereotyped plot of garden ground, though it may be made useful in the following manner. Divide off a third part, or more if you wish, at the north-west end for a vegetable plot. Mark the division by a trellis or lattice fence with a gateway. Encompass the central vegetable plot by a 3-feet-wide path on all sides and at 3 feet distant from the boundary fences. This will give you border room on three sides at all points save where the fowl run exists. These borders may be turned to account for growing bush fruits, Currants, Gooseberries, Raspberries, &c., also herbs, salads, Onions and Rhubarb. Four feet from each corner of the central vegetable plot plant Cox's Orange, Stirling Castle, Lane's Prince Albert and Worcester Pearmain Apple trees, i.e., two cooking and two dessert sorts. At the flower garden side of the lattice-work fence plant *Hiawatha*, *Tausendschön* and its white variety, also American Pillar Roses, to form a screen—this instead of the suggested Rose hedge, for which we think there is little room. In the flower garden portion the side paths may be waved or straight, though in the confined area named the latter would be best. Traverse the turf plot by a path as in the vegetable garden, though of greater width, and arrange crescent-shaped beds of Roses near each of the corners. The side borders could be devoted to flowers, perennials, bulbs, Sweet Peas, Carnations and annuals. These borders might have a turf verge. The best self-clinging creeper is *Ampelopsis Veitchii*; the best evergreen creeper, *Hedera palmata aurea* (Ivy). The prize-winning plans published in our issue for October 17 should assist you.

NAMES OF FRUIT.—R. M. E. Y.—Lamb Abbey Pearmain.—E. Robinson.—1, Belle Julie; 2, Duchesse d'Angoulême; 3, Broom Park; 4, Glou Moreau; 5, Josephine de Malines; Apple, Tibbett's Pearmain.—H. H. Shaker.—Kingston Black.

NAMES OF PLANTS.—M. A. Gordon-Dill.—*Aster Novæ-Angliæ* var.; it is an unnamed seedling and should be increased by division.—John Harris.—1, *Verbena venosa*; 2, *Streptosolen Jamesii*; 3, *Cornus capitata*; 4, *Cestrum Newellii*; 5, *Juniperus chinensis albo-variegata*; 6, *Erythrina Crista-galli*.—X. X.—1, *Daphne Cneorum*; 2, *Polygonum baldschuanicum*; 3, *Daboecia polifolia*; 4, *Veronica speciosa* var.; 5, *Polygonum amplexicaule*; 6, *Saxifraga cordifolia*; 7, *Euphorbia Cyparissias*; 8, *Erica vagans*; 9, *Genista hispanica*; 10, *Erica carnea alba*.—J. B.—1, *Cupressus lawsoniana* var. *alba spica*; 2, *Thuja orientalis*; 3, *Sequoia gigantea*; 4, *Abies Pinsapo*; 5, *Chimonanthus fragrans*; 6, *Cistus salvifolius*.—Mrs. Lawrence, Heyworth.—*Acer monspesulanum*.—Torquay.—*Spiræa prunifolia*.

SOCIETIES.

CHELMSFORD AND DISTRICT GARDENERS' ASSOCIATION.

THE second meeting of the winter session was held in the East Anglian Institute of Agriculture on Friday, the 23rd ult. The president, Mr. E. H. Christy, occupied the chair, and about thirty-five members were present. Mr. C. Wakeley, staff lecturer at the Agricultural Institute, gave an interesting lecture on "The Vegetable Garden and its Present Importance." The lecturer drew attention to the pamphlets, &c., which were now freely circulated, and the advice given with regard to the cropping of every available piece of land with vegetables, in order to ensure a good supply during the war period. He pointed out that caution should be displayed before acting on the advice given, because it was doubtless some two months ago when the advice was written, and therefore some of the cultural operations advised, if carried out now, would be useless. Continuing, the lecturer stated that in the majority of gardens, allotments, &c., little provision was made for the winter crops. A hearty vote of thanks was accorded Mr. Wakeley at the conclusion of the discussion.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the floral committee was held at the Essex Hall, Essex Street, Strand, London, W.C., on Monday, the 26th ult., when a few novelties were staged for awards. In addition Messrs. W. Wells and Co. of Merstham exhibited a collection of two dozen Japanese blooms, for which they were awarded a large silver medal. A silver medal was granted to the Misses Price and Fyfe, East Grinstead, for an exhibit of single and Japanese varieties. The following novelties received awards:

Undaunted.—A large Japanese variety of good depth and size, the broad florets being coloured rich amaranth, with silvery reverse. First-class certificate.

Keith Luxford.—A large, creamy white Japanese flower with excellent florets and plenty of substance. First-class certificate. Both the foregoing were shown by Messrs. W. Wells and Co.

Exmouth Yellow.—This is a splendid single variety of excellent shape and rich yellow in colour. First-class certificate. Shown by Messrs. Godfrey and Sons, Exmouth.

BIRMINGHAM AND MIDLAND COUNTIES GARDENERS' ASSOCIATION.

SOME HINTS ON CHRYSANTHEMUMS.

IN the presence of a large gathering, on Monday, the 19th ult., Mr. Woolman, jun., Sandy Hill Nursery, Shirley, read a very practical and equally entertaining paper, entitled "The Chrysanthemum for Decoration and Exhibition." In order to emphasise the many changes and stages of development which have occurred during the evolution of this flower, he commenced his discourse by reading several interesting extracts from a chronicle of its history. This began at the period when the Chrysanthemum belonged solely to the Orientals. From the time of exportation from China and introduction into civilisation—whence it has reached its present magnificent state of perfection—it has experienced many almost romantic phases of alteration; thus we have to-day blooms of Japanese and incurves that are, according to their species, ponderous in dimensions. Next, dealing with its actual cultivation, he dwelt in graphic detail with all the intricate essentials that concern its growth. First came the initial cutting stage; then the second potting; lastly, the third and final potting. In each case (taken from his own personal method of procedure) he proffered many suggestions as to the sizes of the pots and the preparation of the different composts. At certain times, he added, too, a little feeding would be helpful; but much of the non-success in Chrysanthemum-growing could, he urged, be attributed to the far too prevalent abuse of over-feeding. In considering the Chrysanthemum for exhibition, it is a mistake to think a previous year's record of the maturing of the buds could be used as a precedent for forecasting the results in a succeeding season, as the fickle English climate almost entirely will debar the grower from it. After referring to several well-known favourite blooms of different shades, he concluded his address by making a few additional remarks upon the twelve specimen blooms he had staged within the room. Subsequently, these splendid samples of his efforts were sold, at the suggestion of Mr. Woolman, sen., the proceeds, amounting to 5s., going to the Prince of Wales's Fund, this making the evening's collection up to, in all, 19s. 3d. The audience, before dispersing, expressed their appreciation of the paper by a cordial vote of thanks, proposed by Mr. Cryer and seconded by Mr. Markham.

THE GARDEN.

No. 2243.—VOL. LXXVIII.

NOVEMBER 14, 1914.

NOTES OF THE WEEK.

To Our Readers.—Soon after the outbreak of war we made an appeal to our readers to support the nursery, seed and bulb trade as much as they possibly could by purchasing, if not the usual quantity, at least a good proportion of the Roses, fruit trees, plants, seeds or bulbs that would be bought under normal conditions. It is, therefore, most gratifying to learn from a number of our advertisers that the appeal has borne fruit, and that our readers have realised that, in buying plants and seeds for their gardens, they are providing employment for a thoroughly deserving and hard-working class. We most earnestly hope that the good example thus set will be considerably extended. It is far better to provide work by spending money wisely than to give donations to relief funds, deserving as the latter undoubtedly are. We hope that our readers will remember that every care is taken to exclude unreliable advertisers from our columns, and that those whose announcements do appear can be relied upon to give satisfaction.

An Autumn Snowdrop.—Probably the finest of the autumnal Snowdrops is the form of *Galanthus octobrensis* which is shown in the accompanying illustration. It differs from most of the other autumn species of *Galanthus* in its more robust growth, and also in the fact that its tube, as the illustration shows, is deeply marked with green instead of having only the apical blotch of *G. nivalis*, generally seen in the autumn Snowdrops. It comes from Albania, where it was found by Lord Walsingham in 1875. As the late Mr. James Allen, whose paper on the Snowdrops appeared in *THE GARDEN* of September 19, 1891, remarks, it is of slow increase. Mr. Allen also remarked that it was of delicate constitution, and that Mr. W. B. Boyd found it desirable to lift it and give it a rest after flowering. We have not found this necessary, but it is growing on a dry part of the rock garden where the soil is partly permeated by shrub roots, and where it is naturally well rested in summer.

Christmas Roses.—Where these are grown, a little attention to them at the present time is well repaid later. The top-dressing that was given after the last flowering season should be removed, also any leaves that have collected among the plants. Prick up the soil very lightly with a hand fork, and an application of Clay's Fertilizer or guano will be found very beneficial. As the

purity of the flowers is often marred by mud splashes, hand-lights or frames should be placed over the plants. Air must be freely admitted and the lights removed during mild, dry weather.

An Ornamental Berried Tree.—Although it is ninety years ago since *Cotoneaster frigida* was first introduced from Nepaul, it has not received the attention to which its merits entitle it. For planting in exposed situations it is most

A Basket of Fruit Realises £550.—A sale of a basket of various fruits on behalf of a fund for the purchase of a Red Cross motor ambulance took place in the Commercial Sale Room, Glasgow, on November 4, and realised £550.

Variegated Trees and Shrubs.—When trees and shrubs are being planted for the ornamentation of the pleasure grounds, care should be taken to select a sufficient number with variegated foliage.

There are so many species that have forms of this nature that it should be an easy matter to make a suitable selection. In planting, a much better effect is obtained if the golden variegated forms are planted in full sun, planting the silver variegated ones in the shade.

How the Temperate House at Kew was Completed.—The following extract from the current issue of the *Kew Bulletin* will, we think, be of interest to the numerous visitors who are acquainted with the famous Temperate House at Kew. In writing to the Director at Kew, Mr. Austen Chamberlain says: "I do not know whether you are aware of the full story of the completion of the Temperate House. One afternoon in the House of Commons, Sir William Harcourt, then Chancellor of the Exchequer, asked my father to pair with him for dinner. My father replied that he was afraid he could not do that as he was intending to speak on the motion which was then before the House. 'Oh!' said Sir William, 'don't do that, for if you speak I shall have to stop and reply, and I particularly want to keep my engagement this evening.' 'Well,' replied my father, 'I will make a bargain with you if you like. If you will agree to put money in next year's estimates to complete the Temperate House at Kew, I will pair with you for as long as you wish.' And Sir William Harcourt, nothing loath, assented. My father at once communicated this to Sir William Thiselton-Dyer; but when the next year's estimates came out Sir William found to his horror that the money for the Temperate House had been struck out. He appealed to

my father, and my father to Sir William Harcourt, and the Chancellor, recognising that a bargain was a bargain, directed that a supplementary estimate should be brought in to provide the promised funds. I once suggested to the present Mr. Lewis Harcourt that this characteristic Parliamentary anecdote should be recorded on the Temperate House itself."

GALANTHUS OCTOBRENSIS, A SNOWDROP THAT FLOWERS DURING OCTOBER AND NOVEMBER.

valuable, while its growth being rapid, its habit close and shelter-giving, and its forming a beautiful-shaped specimen even in almost pure clay are worth bearing in mind. The flowers, which are in creamy white corymbs, are followed by a bright display of scarlet berries, making the tree particularly interesting from September onwards.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Peas and Young Vegetable Marrows in November.—As a proof of the mildness of the autumn weather, we are able to gather Peas Ne Plus Ultra in November, and also Vegetable Marrows in a young state, not old and hard as they are when matured. I have, twice in thirty years, had the experience of growing Pea Ne Plus Ultra in freshly broken land with great success, and in old vegetable quarters, where the soil was full of humus, without real success. In the latter case the seeds rotted in the soil, in both high and low positions, to a big percentage. In the new soil all seeds germinated and the plants flourished. Those that did grow in the old garden loam lacked vigour. The seeds were not faulty. The Marrow plants were raised late in the summer, and have fruited well very late.

—G. GARNER.

Apple Trees in Bloom in October.—I have recently gathered some ripe Apples off a young tree which is bearing young fruits about the size of small Walnuts, and trusses of flowers of the most lovely deep colour. In its proper season this variety bears very large, beautiful flowers, but I have not seen larger blossoms than the ones open on October 28, nor richer in colour. There are also flowers on other trees.—G. G.

Salvia Fireball.—This brilliant scarlet *Salvia* has made such a brave show here this past season that I cannot refrain from penning a line in its favour. The plants were raised from seed sown in the first week of February, and were in due course potted off into 3-inch pots and hardened off along with other bedding plants. In the last week of May they were planted out in a border filled chiefly with half-hardy annuals. For the first week or two the plants made little progress, but by the middle of July they were flowering freely, and from that time up till the date on which I am writing (October 19) they have made a dazzling show. I have taken a batch of cuttings, and hope, during the next season, to make a comparison between plants raised from cuttings and those raised from seed. The plants have attained a height of 18 inches or more on deeply cultivated ground.—CHARLES COMFORT, *Davidson's Mains, N.B.*

Recipe for Medlar Jelly.—In THE GARDEN for last week Mr. Molyneux gives us a recipe for Quince jelly. Another fruit, which is generally wasted, but which makes a most delicious jelly, is the Medlar. Well-made Medlar jelly is in flavour like the best Guava jelly, and quite its equal as a preserve. The fruits should be fully ripe, in the same condition as when used for dessert. Prepare the fruits and boil them with enough cold water to cover them, and to every two dozen Medlars allow the thin rind and strained juice of half a Lemon. Boil well, and strain without any pressure then put the juice in the pan with its weight of sugar, and add more strained Lemon juice in the proportion of one Lemon to every fifty Medlars. Boil and keep skimmed. The jelly should be quite clear, but if the least

sediment is put in, it will fail in this respect. Time, about an hour and a-half to boil, but it varies. Great care should be taken that it does not burn.—C. B.

Mistletoe Growing on Ampelopsis Veitchii.—This parasite grows on many more kinds of trees than is generally supposed, but I have never seen or heard of it being found growing on *Ampelopsis Veitchii* before. When at Rood Ashton, near Trowbridge, in the early part of October, I saw a fine plant growing on this *Ampelopsis*. The mansion is covered with the climber, and near the top, on the south side, is a fine plant of Mistletoe, sufficiently large to be seen at a long distance. Mr. Strugnell, the gardener, chronicled the incident in one of the gardening journals early in the year. When we were looking at it, he remarked that it had made considerable growth this season. Naturally, many may ask how this could have got into such a position. Un-

WILD BELLADONNA LILIES THAT WERE GATHERED IN SOUTH AFRICA.

doubtedly from some bird carrying the berries from bushes on trees near by in the park. Some fifty years ago, when a youth in these gardens, I well remember how abundantly Mistletoe could be seen in the fine old Limes and Thorns in the park. I have not seen them so fine anywhere since. I noticed that several of the Thorns where it grew best had gone, and some Limes had been cut down.—JOHN CROOK.

When to Plant Tulips.—"Observer," writing in THE GARDEN for October 31, page 528, thinks he has caught me tripping, and in a way I confess that my advice given on this subject in your columns a few weeks since and the advice given in our bulb catalogue may seem at variance, owing to the wording of the same, which I admit to be faulty, and am grateful for having it pointed out. On the other hand, if "Observer" will look again at the page he quotes, he will see that the heading is for bedding Tulips, and the little bit about home-grown Darwins was only illustra-

tive of a certain point. The planting-time given was meant to refer to bedding Tulips only. It is quite possible that these (bedders) might be benefited by earlier planting than October or November, but it would be obviously unwise to advise people to plant bedding Tulips at a time when, in the average season, their beds would still be bright with summer plants. My own practice in planting several acres of Darwin and other late-flowering Tulips is to begin as soon as the Daffodils are in, which is generally about the first or second week in September. This year we began a little later, September 22, and finished on October 9, and I intend to stick to this until experience teaches me that later planting is better for the crop of flowers and bulbs. Up to the present I am fully satisfied that early planting is better than late. If "Observer" will refer to our catalogue next year, I hope he will find the advice given as to the time of planting so clear that no one can mistake the meaning of it.—

J. DUNCAN PEARSON (of the firm of J. R. Pearson and Sons), *Lowdham, Notts.*

Habitat of Amaryllis Belladonna.—I noticed that you mentioned in your issue of October 17 the flowering of the *Belladonna Lily* at Kew and in Ireland this year, and your correspondent Mr. Bryan states that this plant is supposed to come from the West Indies, and to have been introduced to South Africa from there, as it has never been found growing wild in South Africa. I am sure he is mistaken in thinking that it has never been found growing naturally in South Africa. It is certainly indigenous on the mountains of the Cape Peninsula. I have found it growing there in great quantities, and enclose a photograph showing a cluster of these flowers which had just been gathered on the adjoining hillside.—PERCY A. MOLTENO.

— Your correspondent Mr. Samuel Bryan, on page 502, says that "all botanists agree that *Amaryllis Belladonna* was introduced into the British Isles from the West Indies in 1712, and it is very probable it was brought from England to the Cape of Good Hope, but we have no authentic information as to its ever being found growing naturally there." The term "all botanists" is too sweeping an assertion, for in the "Kew Hand List of Tender Monocotyledons" it is

stated to be a native of South Africa. Surely Kew contains some botanists worthy of being included in the expression "all."—H. P.

Finger and Toe Disease in Green Crops.—The article by "A. E. B." in your issue of October 24, page 519, should be helpful to all who have to contend with this foe. In addition to the remedy given, I may add that, having to deal with soil where this is very troublesome, I have found several things helpful to check the pest. For many years I was quite in the dark as to the cause (which is of the first importance in dealing with all diseases, &c.). Having realised its nature, the question of a remedy arose. I have come to the conclusion that where green crops have to be frequently planted on the same soil, trenching the land every two years 2 feet deep and planting the same season as this is done is one of the best methods to keep it down, and in time I believe would eradicate it out of the soil. About two years ago, when at Sutton Place, near Guildford, while going

through the kitchen garden with Mr. Goatley, he told me that when he took charge there this disease was most troublesome, but by continually trenching the land he rarely saw a clubbed plant. Although a dry summer I could not see one. About four years ago, on some land I work I had a portion trenched 2 feet deep. On this all sorts of the Cabbage family were sown, and I did not see an infected plant that season.—J. CROOK.

Roses and Mildew.—Although I am afraid "Somerset" might as well ask for Roses immune from attacks of green fly as from mildew, I am sure some varieties are more prone to the mildew trouble than others. In the Rose notes which are published in THE GARDEN from time to time it is frequently mentioned that most Roses with dark green, leathery foliage are very free from mildew. My own experience bears this out, and Mme. Ravary, Le Progrès, Mrs. David McKee, Prince de Bulgarie and Mme. Melanie Soupert are with me quite satisfactory. Although their foliage is not so smooth and thick, the following are also very free from mildew: Mme. Abel Chatenay, Caroline Testout, La Tosca and Frau Karl Druschki.—CHESHIRE.

— I have read lately with interest some letters in THE GARDEN about mildew on Roses and the apparent difficulty of dealing with this plague. I sympathise with the gentleman who does not want to spray his Roses once a week all through the season. But what is to be done to large climbing Roses—Maréchal Niel, Rêve d'Or and Celine Forestier? The latter began it in the early spring, and was so bad that it had to be removed. These were on the south side of the house. On the north side Gloire de Dijon was barely touched by it. The ramblers all had it badly, and Tausendschön was the worst of the lot. Of the bush Roses Lady Ashtown was the worst, Mrs. David Jardine next, then Laurette Messimy, then Mme. Ravary, then La Tosca, then Pharisæer. General Macarthur and Comtesse du Cayla were practically untouched, and Perle d'Or absolutely untouched (twelve of them). William Allen Richardson and a Yellow Banksian are also untouched. Caroline Testout in standard form was ruined.—C. AMBROSE, Brookwood, Surrey.

— Lieutenant Chaure is a red Rose which, I venture to predict, will soon be in every Rose garden. We are badly off for red Roses of the Hybrid Tea class, and one that has all the excellent characteristics of Lieutenant Chaure cannot for long be neglected. Your correspondent "Somerset" asks for names of Roses which are mildew-proof. I will not go so far as to claim that Lieutenant Chaure is "proof," but in a year when Roses have been badly attacked in most gardens by mildew and black spot, it has, in my garden, been practically free from both diseases. For the information of those who have not got this Rose, I may add that it was sent out by M. Pernet-Ducher in 1910. Its reputed parentage is Etoile de France × Liberty, which is not calculated to impress one with its hereditary virtues! It has not, however, the faults of either parent. While not being particularly full, as exhibitors count fulness, it can be grown right up to exhibition form. Its stout, deep petals stand well, and the Rose when cut seems to last longer than many Roses of greater substance. It opens well in all weathers—a trait it certainly does not inherit from Etoile de France—flowers very freely and continuously; and has a delightful fragrance.

In Mr. Mawley's special audit of twenty newer Hybrid Teas, given in this year's "Rose Annual," it only came out nineteenth in the voting. This is surely too low a place. I have found it a better and more reliable Rose than either Edward Mawley or Leslie Holland. The colour may be described as a velvety crimson red, which, I think, it retains longer than most reds. Its growth is strong, even and compact, which makes it an admirable Rose for bedding purposes.—CHARLES H. RIGG, The Grey House, St. Mary Church, South Devon. [We quite agree with our correspondent in his praise of Lieutenant Chaure. We have found it an excellent Rose.—ED.]

— I am glad to note "Somerset's" few words upon this on page 528, issue October 31. A good many Roses are claimed as mildew-proof; but while a large number are little affected by this disease, unless in exceptionally uncongenial conditions of weather and extremes of temperature, I fear we cannot claim absolute exemption. From many years' observation I find the first few named below the freest of any: Duke of Wellington (it is curious that Fisher Holmes, in many other respects similar to Duke of Wellington, should be so subject to this disease), Ulrich Brunner, Arthur R. Goodwin and its grand yellow sport J. F. Barry are quite free here. Mme. Ravary, notwithstanding its beautiful soft and bronzy foliage, is remarkably free both in town and country. Melody, Mrs. Cornwallis West, Rayon d'Or, W. E. Lippiatt and Mme. Constant Soupert are very seldom touched. I also find Boule de Neige, Coquette des Blanches and Perle des Neiges beautifully free among the pure whites. The freest among our climbers are Félicité Perpétue and the three wichuraianas Alberic Barbier, Gardenia and Jersey Beauty. That grand all-round climber and pillar Rose American Pillar is as free as anything here. A good climber seldom touched is found in Excelsa. A few others scarcely ever mildewing with me are Alfred Colomb, Duke of Edinburgh, Captain Christy, Hon. Ina Bingham, La Tosca, Mrs. Alfred Tate, Mrs. Amy Hammond, Mrs. David McKee, Mrs. Frank Workman, Mrs. Theodore Roosevelt and Zephyrine Drouhin. Most of the Penzance Briars, especially the beautiful Lady Penzance, are free; also the Scotch Briars and Rugosas. Among the continuous-flowering Dwarf Polyanthas, too, there is very little mildew, if we except Mme. N. Levavasseur, which I have found very bad in most seasons.—A. P., Uckfield.

Francoas as Hardy Plants.—For the last two or three years we have utilised Francoas for garden decoration in the open air, retaining them in the ground during the winter without any protection. The site is a sunny one, but open and windswept, and the soil is loam resting upon heavy clay, hardly the ideal for Francoas in the winter according to general ideas; but my experience of them has been so good that I would urge garden-lovers to give the Francoas a trial in the open garden. The forms used have been Francoa ramosa (the charming white-flowered Bridal Wreath), F. appendiculata and F. sonchifolia, the pinkish forms, which seem to be equally hardy. Out in the open the mounds of foliage are very compact and close to the ground, and the wealth of blossom is immense, giving a continuous display of the dainty flower-spikes. Exactly how much frost they will stand I cannot say, but I remember a bed of F. sonchifolia coming safely through the last severe winter experienced in the South of England.—P. S. HAYWARD.

TEMPORARY WIND SCREENS IN GARDENS.

IN many gardens, and particularly those near the East and South-East coasts, it is impossible to grow a number of plants successfully unless a screen of some kind is provided to break the force of the keen, biting winds of winter and early spring.

These winds, if allowed to ravish an exposed garden unchecked, often do far more harm than the severest frost, and this is particularly noticeable during the early months of the year, when a brief spell of mild weather induces buds to sprout prematurely. In gardens which have been established for some years, and where it is known that dangerous winds prevail in certain quarters, a permanent screen in the form of a belt of Scotch Pines, or a thick hedge of Yew or Berberis, will have been planted; but even in such instances temporary screens such as I have in mind are most useful for protecting beds or groups of plants at those times when they are most susceptible to injury. In these situations a permanent screen would not be permissible, inasmuch as it would not be required for more than a few weeks of the year, and during the remainder of the time would be quite out of place, if not an actual eyesore. Daffodils, Tulips, particularly those of the Cottage and Darwin sections, early flowering shrubs, such as Magnolia stellata, and choice fruit trees are plants that occur to mind as needing temporary shelter of the kind mentioned.

Although there are several proprietary articles that answer very well as temporary wind screens, those who live in the country may well utilise the material that Nature in most districts provides so lavishly. In modern gardening, as in most other things, there is too great a tendency to ignore natural material, and to rely upon that which is manufactured. The latter may answer the purpose for which it is intended very well, but it never appears so much in keeping with natural subjects as the protective material that can be had for the culling from our hedges, commons and copses. The most serviceable natural wind screens for garden purposes that I have seen took the form of withy hurdles, the Hazel and Willow withes being cleverly plaited so that when finished each hurdle was about three feet high and five feet long. These screens would last in good condition several years, but in a small garden the storing of them during the summer and autumn months proved somewhat embarrassing. A stout stake thrust well into the soil on either side of the hurdle, and at each end, held it firmly in position when required for shelter.

Of a more temporary character were screens of dry Bracken gathered from a copse near by. This was made into screens of about the same size as the withy hurdles by running stout branching sticks along either side of the Bracken and lashing them tightly together with stout tarred string or Cocoanut fibre rope. A long, pointed stick of some hard wood, with a large eye near the point similar to a sewing-machine needle, was used for pushing the string through the Bracken, so that the sticks on one side of the screen were firmly tied to those on the other. It is surprising how quickly a couple of labourers who are used to hedging work will make a number of these screens, which will last good a whole winter and spring, and which can be used for farm as well as garden purposes should the necessity

for doing so arise. The screens could, of course, be made any size that is required, but it is not often that any of a larger size than that named are needed, though some smaller are useful.

Where Bracken is not obtainable, there is usually an abundance of other material to hand. Heather or Ling answers well, and long grass such as is trimmed from the sides of hedgerows may also be requisitioned, though there is in this case a danger of weed seeds being distributed over the garden. Gorse and Yew branches make excellent wind screens, and although the first-named must be bound together as advised for the Bracken, the Yew branches can, if necessary, be used separately, one or two thrust well into the soil on the windward side of some choice plant providing a screen that is at once effective and natural in appearance. Branches of Scotch Pine, Berberis Aquifolium, or, indeed, those of any evergreen that is present in sufficient quantity, may be utilised in like manner. In the seed-growing districts of Essex the hard, wood-like stalks of Carrots that have been grown for seed are used largely for making screens for agricultural purposes, these being lashed together with sticks similar to the screens of Bracken. They are hard and last a long time if kept straight and tightly tied, and would be equally as valuable in the garden as on the farm. No doubt in various counties there are other kinds of material that could with a little ingenuity be utilised for temporary wind screens, the use of which may mean the difference between seared and blackened foliage and healthy, free-blossoming plants. Attention is drawn to these screens now while the material is available. The making of such protections from wind provides work for the men at a time when little else can be done.

B. G.

NEW HERBACEOUS BORDERS.

HOW TO MAKE AND PLANT.

WHILE we have fresh in our minds the different herbaceous borders as they have appeared during the past summer months, we should make our plans for the construction of new ones. This

A BORDER OF MIXED FLOWERS AND SHRUBS. NOW IS THE TIME FOR PLANTING.

refers to cultivators who do not possess such borders and to those who do possess them but wish to make new ones or renovate existing borders. The preparation of the soil, the selection of plants and their disposition in the borders are the three principal points that the cultivator must pay the closest attention to when engaged in making the new borders.

Positions for the Borders.—Ideal ones are not available in every garden, and so the most must be made of the best ones. The following positions are good ones, namely, (a) in front of a wall facing south, south-west and south-east; (b) on one or both sides of a garden path running north and south or east and west; (c) in front of a gently winding shrubbery.

Positions that are Unsuitable.—(a) Under rows of fruit trees in the vegetable garden, but

suitable if the trees are far enough back from the path in the case of bush and pyramid-shaped trees. Espalier-trained fruit trees, distant from 8 feet to 12 feet from the path, form a good back-

ground to herbaceous borders. (b) Under large deciduous and evergreen trees growing near the edges of shrubberies, as not only do their roots rob those of the herbaceous plants, but their branches also prove inimical to their welfare. (c) In very shallow, poor soils, situated also on high ground. If there are no means of deepening and enriching such soils, the plants fail wholesale after the month of June.

How to Prepare the Soil.—The present is a good time for the trenching of the soil, so as to have it in fit condition for the plants in the course of a week or two. Whether broad or narrow, the borders should be trenched by commencing the work at one end and finishing at the other. A trench must be opened and the soil wheeled to the other end for filling up at the finish. Dig the soil at least 2 feet deep, but keep the subsoil below, breaking it up thoroughly. Use good manure, partly rotted, and well mix it with the soil just below the surface and not deep down, as the plants could benefit little if it were thus placed, the nutriment being washed down out of the reach of their roots.

How to Plant.—This and the arrangement of the plants are two items of great importance, as the work should be done so as to provide an unbroken supply of blossom during the greater part of the year. There are two ways of marking out a border for the plants, as shown in Figs. A and B, respectively. In every instance the

tallest-growing kinds of plants must be allotted the back portion, the medium the centre, and the dwarf the front. There will never be a uniform height that will make all plants have a stiff appearance, as some will always vary in strength and height. Fig. A shows at No. 1 the back part marked out formally for clumps of such plants as Michaelmas Daisies, Delphiniums, &c.; No. 2, large clumps of Phlox; No. 3, bulbous plants in clumps, such as Gladioli; No. 4, the smallest growers, such as Alyssums, Anemones, Armerias, Arabis and dwarf Campanulas; No. 5, Veronicas and the medium kinds of Aster, such as A. acris, A. Amellus, &c. A bed of this kind would have a bold appearance when the plants in it were established.

Fig. B shows a bed which would be filled with much less formality—smaller clumps and greater mixture. The dotted lines drawn through the

FIG. A, SHOWING ONE METHOD OF PLANTING HERBACEOUS AND BULBOUS FLOWERS.

FIG. B.—A LESS FORMAL METHOD OF PLANTING. FOR DETAILS SEE TEXT.

bed show, however, how the cultivator must arrange the plants, namely, No. 1, dwarf; No. 2, the taller of the accepted dwarf kinds; No. 3, those of medium height; and No. 4, the tallest. If these all overlap a little, as shown, the general effect is quite charming.

G. G.

THE GLORY OF THE SNOW.

AMONG those bulbous flowers of lowly stature which open early in the spring and remind us that winter, with its gloom and fog, will soon be a thing of the past, there is none that receives more universal admiration than the charming little Glory of the Snow. Its popular name, unlike many, is an expressive one, for frequently in its native haunts, and occasionally in this country, the dainty little bell-shaped, pale blue and white blossoms may be seen above a foil of driven snow, which enhances their beauty in no small degree. Boasting the rather long and sonorous botanical name of *Chionodoxa Luciliae*, this little plant has been known in our gardens for many years, yet it does not appear to be grown on an extensive scale, except in a few gardens where more or less rare plants are appreciated. It usually blossoms early in March, when the Snowdrops are waning, and is never so happy as when planted among deciduous shrubs, where it will multiply and in a few years form a veritable carpet of blue. There is a very large-flowered variety of it that appeals to many, and which is known as either *grandiflora* or *gigantea*. The blossoms of this are frequently $1\frac{1}{2}$ inches across, and somewhat paler in colour than those of the type. The most pleasing variety of all to me, however, is the beautiful little *sardensis*, the original bulbs of which, I believe, were found near the ruins of the ancient town of Sardis. The blossoms of this, though smaller than those of *Luciliae*, are of an intense gentian blue, and when massed together create a picture of rare beauty. In a narrow south border, which is all the space I can give them at present, the plants of this variety seed freely, and hosts of young plants are produced naturally from the seeds. There are several pink and white varieties of the Glory of the Snow, but these do not appeal to me in the least; they are washed-out imitations of the wild plant and are not nearly so pleasing. Fortunately, the *Chionodoxas* are not particular as to the soil in which they are planted, but they rarely give their best flowers the first year after planting.

H.

APPLE LANE'S PRINCE ALBERT.

It would be difficult to name a better all-round Apple for a small garden than this. It is one of the most regular croppers that we know, and, owing to its rather straggling habit, is best grown as a bush tree grafted or budded on Paradise stock, as shown in the accompanying illustration. The fruits attain a good size and are green, slightly striped with red, the green changing to a pleasing shade of yellow as they ripen. They are in season from November till March, and, though undoubtedly a culinary variety, are not at all bad for dessert in January and February. Lane's Prince Albert was first discovered growing in a garden at Berkhamsted, Herts, and was introduced to commerce by Messrs. Lane and Sons in 1857. Those who are thinking of planting Apples this autumn should certainly include this variety.

FRUIT NOTES FOR NOVEMBER.

Cordon Gooseberries.—In practically all small gardens there is a north wall or fence from which the amateur fails to secure a profitable return; he does not find many climbers that will thrive satisfactorily in such a position, and the consequence is that in the majority of instances the space is occupied by a plant that is neither really beautiful nor substantially useful. It is for such an aspect as this that cordon Gooseberries can be most strongly recommended, since it is certain that, given intelligent management, they will carry splendid crops of fruit later than can be ensured from the bushes growing in the open, and as they are from a previously unprofitable situation they should be specially welcome. Two year old plants ought to be procured from one of the reliable fruit nurserymen advertising in THE GARDEN, and

proportion of available food, of which the trees will have the advantage. It is far better, in my opinion, to dig above the roots, even though a few dozens may be broken, than to allow the weeds to remain and the surface to become so hard that it is impervious alike to air and water.

Planting Raspberries.—October is without doubt the ideal time for planting new Raspberry plantations, but it is comparatively seldom that it is possible, in the pressure of much work in that month, to accomplish the task, and it must, therefore, be done as soon afterwards as can be made convenient. It is impossible to cultivate the soil too deeply or thoroughly, and in its preparation, if a mixture of half-rotted leaves and manure in equal proportions can be provided, it will prove more advantageous than manure alone. Immediately after the canes are in position, the stems should be cut down to within 6 inches or 8 inches of the ground, with a view to allowing the plants to become perfectly established at the roots before

A BUSH TREE OF APPLE LANE'S PRINCE ALBERT. THIS IS AN EXCELLENT VARIETY FOR SMALL GARDENS.

planting should be done as quickly as possible. Prepare the soil by deep and thorough digging, incorporate some rotted manure in the second spit, and it will not be long before a return for the small outlay is being reaped. If the wall is of brick, the grower must be most particularly observant that the soil about the roots never becomes as dry as dust.

Digging Among Roots.—To suggest this will sound like heresy in the ears of many cultivators, who fear that to damage a single root on any of their Apple or Pear trees will mean instant death. But is this really so? Most assuredly it is not. Provided that proper care is taken and the blade of the spade or the tines of the fork are not driven in so deeply as to do serious injury to the root, nothing other than good will result from the practice. Not only are water and air encouraged to enter more freely, but the weeds that are almost sure to be present can be easily and efficiently buried, and in rotting down they will yield a

they are called upon to bear the strain of cropping; this precludes the possibility of any fruit in the first season, but it pays admirably in the long run.

Wall Trees.—It is steadily becoming more general to find a few trees on the walls of small gardens, for the simple reason that amateurs have learned that with a little care not only can the wall be attractively furnished with fruit trees, but that these will bear a welcome burden practically every season. At this juncture the grower must concern himself with the roots as well as with the pruning of the branches. As soon as this latter work is done, the soil above the roots should be loosened with a fork and have a good covering of manure. As it is quite probable that the soil at the foot of the wall will be dry, it is always wise to make certain on the point before manuring and to apply two or three soakings of clear water if necessary; and if the trees are on the old and weak side it will be beneficial to give heavy applications of liquid manure.

FRUIT-GROWER

IN A HAMPSHIRE GARDEN. SOME OF THE NEWER DECORATIVE ROSES.

(Continued from page 541.)

It is only a year or so ago that I remember writing to a friend "there are only two yellow decorative Roses worthy of the name, and they are Mme. Ravary and Souv. de Pierre Notting," and even these I had to qualify. The position is very different to-day, and we have now quite a lengthy list of Roses of a yellow shade that are really good yellow decorative sorts. Last week I dealt with four of them—Melody, Mme. C. Lutaud, Mrs. Ambrose Ricardo and Lady Hillingdon—all of them quite distinct, each with its own particular merit; and this week I will deal with four more, still keeping to the yellow shade of colour. Probably the most popular in future years will be

Queen Mary, sent out in 1913 by Messrs. A. Dickson and Sons of Newtownards. It is truly a "thing of beauty." I do not know of any Rose that I remember to have grown which has created more of what I must call a sensation, for want of a better word, in the eyes of those who were looking at it for the first time. There is something about its colour that is so charming that an exclamation springs to the lips, be they Rose enthusiasts or otherwise. To attempt to describe this charm on paper is an impossible task. Even those past-masters in the art, its raisers, fail, and where they do so, how can I hope to succeed. They call it bright canary yellow crayoned with pure deep carmine, and they go on to say that the colours do not commingle. A crayon is a pencil, and its markings are certainly distinct and do not mix like those laid on with a brush; but there is, as a rule, a hardness about a pencil mark that is missing from the colour scheme of Queen Mary, and so I must give it up, and content myself with saying truly and literally "indescribably beautiful."

Queen Mary belongs to the dwarf section of bedding Roses. The growth is medium rather than vigorous, yet it is shapely enough, and the term "medium" carries with it in this case no disparagement. It is, I know, frequently used by nurserymen when they wish to describe a Rose of bad growth, but there is nothing bad in this case. The Rose simply puts all its strength into its flowers, and it does not, therefore, make a big bush. It forms seed-pods very freely, and these must not be allowed to remain; but the flowers, if they are not cut as buds or half-opened blooms, should be cut as soon as they are past their best, to enable the plant to make that fresh growth which is essential if you are to have continuity of flower. The position is fairly summed up by a Professor friend of mine, whom I heard remark that he was not going to order any new Roses this year, but he *must* have

Queen Mary. As he planted several hundreds last year, there was some excuse for the first portion of his remark, and if there are any of your readers who are similarly situated, I hope they will follow his example and change their minds. We must all fill up vacant spaces in our gardens, and no hardy plants can touch a Rose plant for this purpose.

Southampton. HERBERT E. MOLYNEUX.

(To be continued.)

ROSES IN A GARDEN ON SURBITON HILL.

WHAT a host of happy memories the photograph of a garden of Roses on Surbiton Hill, on

ROSE GLOIRE DE DIJON AND CLEMATISES ON A PERGOLA.

page 495, October 10 issue, awakened in me!—for I grew up in an old-fashioned garden full of Roses there. Dear old garden! innocent of "colour schemes" or cunningly devised plan. "Specs it growed," like Topsy; indeed, I *know* it did, from a paddock, gradually turned into a garden, where flowers and fruit trees, Roses and vegetables were all mixed up together in a manner which would horrify modern gardeners. Antirrhinums jostled Jerusalem Artichokes. Such Antirrhinums! Not the poor, dumpy dwarfs nor the sickly, spindly spires one sees now, but great jolly bushes a yard in diameter. They lived year after year in that sunny, sheltered garden and yielded a wealth of blossom from

early summer till close on Christmas. There, too—long before bulbs were "naturalised" in grass—for childish fun and fancy I planted "fairy rings" of white Crocus round the boles of the trees on the lawns.

But I set out to tell of the Roses, which were the leading feature of that old garden. My mother was a Rose-lover, and very skilful in budding the standards, which were the fashion then. She got scions of new varieties every season for the row of Briars always in readiness to receive them. Among the then "new" Roses was Baroness Rothschild, soon discarded in disgust when found to be scentless. That is the first scentless Rose I can remember. The tennis lawn was bordered by beds of Roses, among which

Mint would insist on growing, though it sulked and died in the herb-bed. Particularly I call to mind two immense standards of Aimée Vibert, which in the summer looked like gigantic wedding bouquets and flowered again in the autumn till the end of the year, and a tall bush of Souvenir de Malmaison, with its beautiful buds, in the autumn. Bushes, too, there were of Scotch Briars with their wee white buds and dainty, though thorny, foliage. Beside them flourished a large Myrtle, whose flowers were in great request for summer weddings. When thunderstorms threatened, my mother would bid me "run and get the Roses before it rains," and I quickly cut hundreds, gathering them up in the front of my frock (we did not wear hobble skirts in those days). By the drawing-room window was a climbing Cabbage Rose, always in flower on Derby Day, and at the back of the house a pale pink, sweet-scented cluster Rose climbed to the first-floor windows. I never knew its name.

In the kitchen garden were two ancient Rose trees, literally *trees*. They were about ten feet high. One had blackish crimson blooms, with the scent of attar of roses. The other was more like Mme. Resal or Leonie Lamesch, a shell pink, loose-petalled Rose with smooth, shiny foliage (the children called it the "French Bonnet" Rose, as it was like the artificial Roses in our mothers' best bonnets), a type of Rose not well known nor esteemed then. In that old garden every

year I had a hedge of my dearly loved Sweet Peas, not then deprived of form and fragrance by Fashion. They grew only 4 feet to 5 feet high, and flowered from the ground upwards, a glorious mass of mingled rainbow hues, especially when the sun was setting behind the water towers.

At the Jubilee Ball at the Guildhall, London, in 1887, many folks were more finely arrayed than your Anne, but none wore lovelier Roses—a long garland a-down my green gown of some fifty creamy buds of Devoniensis, given me by old Mr. John Burrup of Surbiton Hill, who was the leading amateur Rose-grower there at that time. His garden in June was a floral feast.

ANNE AMATEUR.

PLANTS FOR DRY OR SANDY SOIL.

IN a great many gardens, and particularly those attached to modern residences, where owner and architect rightly insist on a gravel subsoil, the ground is by no means ideal for gardening, and unless care is exercised in selecting the plants, partial or total failure is likely to ensue. It is true that even the most sandy soil can, by good cultivation, which includes bounteous dressings with cow-manure, be rendered comparatively fertile, and, with the addition of stiff loam to the beds in the more prominent situations, these can be made good enough even for the clay-loving Roses. But such a revolution as the last-named process must, of necessity, be limited; it is exceedingly costly, and in the greater part of the garden the best must be made of the natural soil. Fortunately there are many plants which seem quite happy in sandy or gravelly situations, and these embrace those of annual duration, herbaceous perennials and shrubs, so that with judicious care the whole of the garden can be made beautiful and interesting.

Among annual flowers there are many to select from. Perhaps the best known of all is the common *Tropæolum* or so-called Nasturtium, a plant that is too often neglected, possibly because it is so easy to grow. It is ideal for sandy soil, where it will flower profusely and impart quite a tropical appearance to the garden. Sow it in rich soil and it will produce enormous leaves in abundance, but very few flowers. It can be had in separate colours, and is a good and useful plant for the poorest soil. An annual flower, and a beautiful one withal, that is seldom seen, but which will thrive in the hottest and driest position we can give it, is the Purslane (*Portulaca grandiflora*). If seeds are sown about the end of April, the seedlings soon form a dense carpet of fleshy green leaves, which are later thickly studded with brilliant-coloured flowers. *Eschscholtzias*, though strictly perennials, are usually grown as annuals. Their thick, fleshy roots penetrate deeply in search of moisture, and for that reason they are good for the soil that we now have under notice. There are a number of beautiful varieties to select from, including some with rose-coloured and others with brilliant orange flowers. The Snapdragon is another perennial that is usually grown as an annual and which will thrive well in poor soil, particularly where lime is present. The many beautiful shades to be found among the modern varieties are too well known to need further comment. Indian Pinks, Early Paris Wall-flower, Ten Week, Virginian and Night-scented Stocks, *Leptosiphon densiflorus hybridus*, Cornflowers, *Silenes*, Scarlet Flax and the Namaqualand Daisies are other annual flowers that we may successfully cultivate in our sandy soils. When we come to herbaceous perennials, there

is a wide list to select from, and in an article of this description it is impossible to do more than draw attention to a few of the best. The Sea Hollies or *Eryngiums*, Globe Thistles or *Echinops*, perennial Sunflowers, Golden Rod, *Gypsophila paniculata*, Pinks, *Stachys lanata*, Valerian, any of the Houseleeks, *Polygonums*, ordinary Wall-flowers, Alpine and Oriental Poppies, the red-flowered Milfoil and *Achillea Ptarmica* The Pearl, *Sedum spectabile*, *Gaillardias*, *Heucheras*, German Irises, *Linum narbonense*, perennial Lupines, *Lychnis chalcedonica*, *Malva moschata*, *Monarda didyma*, Catmint, *Polemonium cæruleum*, *Potentillas*, and *Rudbeckias* or Coneflowers are all good for the purpose.

Among shrubs, our choice of suitable kinds is more restricted, but there are a good many which can be successfully cultivated. Of these, the double-flowered Gorse must take a foremost position.

CULTIVATION AND COLLECTION OF MEDICINAL PLANTS IN ENGLAND.

[The following has been recently published as Leaflet No. 288 by the Board of Agriculture.]

BELLADONNA (ATROPA BELLADONNA, L.).

(Continued from page 549.)

Prices.—Only a little Belladonna root is dug in England, the large supplies used being derived from the Continent. The Balkan War of 1912-13 interfered with the continuity of Belladonna exports from Croatia and Slavonia in South Hungary, the chief centres for foreign Belladonna. Stocks of roots and leaves made shorter supplies eke out until 1914, when prices rose owing to increasing scarcity. Root which realised 45s. per cwt. in

A COLONY OF SUN ROSES OR HELIANTHEMUMS. THESE ARE EXCELLENT FOR DRY, SANDY SOILS.

Once established, it seems to defy even the most tropical weather, and the poorer the soil the better it appears to flower. Then there is a wide range among the *Cytisus* or Broom family, some of which are the most beautiful of our hardy flowering shrubs: *Cytisus scoparius andreanus*, *C. sulphurea* and *C. præcox* are three of the best, though there are many others; *Berberises vulgaris*, *Aquifolium*, *stenophylla* and *Darwinii* may also be planted with a good prospect of success; *Cistuses*, *Helianthemums* or Sun Roses, *Tamarisks*, *Olearias*, *Hypericums*, *Genistas*, *Guelder Roses*, *Mock Oranges*, *Dogwoods*, *Hollies*, *Forsythias*, *Yews*, *Aucubas*, *Cotoneasters*, the ornamental *Brambles* and *Lilacs*. Of trees, the following may be expected to do well in poor, sandy soil: *Robinias*, *Limes*, *Chestnuts*, *Sycamores*, *Cratægus*, *Judas Tree*, *Pinus sylvestris* and *Evergreen Oaks*.

January, 1914, sold for 65s. in June, and on the outbreak of war the price immediately rose to 100s. per cwt., and before the end of August 150s. had been paid. Belladonna leaves from abroad sell at normal times for 45s. to 50s. per cwt., but at the end of August they were unobtainable at 1s. per lb.

Manuring.—Authorities differ on the question of manuring. English growers manure little if plants are strong. One authority found that fertilisers tend to lower activity as judged by alkaloidal content. With soil suited to the plant, the effect of artificial manures on growth is often small; but if the soil is not already rich, the crop may be increased severalfold by the use of farmyard manure or a mixture of nitrate of soda, basic slag and kainit.

In other experiments artificial fertilisers did not materially alter the proportion of alkaloids

in the green leaf, but in several cases the crop was largely increased in weight. Unfortunately, the results were partly vitiated by the death of a large proportion of plants in the third year, for some reason not definitely ascertained. A French authority states that by using farmyard manure the amount of alkaloids in dried leaves of Belladonna grown at Houdan, France, was doubled, but this only raised the alkaloidal content to the standard of English leaf. From experimental plots an Austrian investigator concluded that manuring increases the yield of the crop by weight. The results of these researches seem to support the custom of Belladonna-growers to manure if the soil is poor or the plants are weak.

Activity.—There appears to be no marked variation in the amount of alkaloids in Belladonna leaf and stem between June and September, hence the time of collection is not important,

probably pay well to grow Chamomile next year, though the labour entailed in collecting English-grown Chamomile is more than the price usually obtained for the Belgian drug. English Chamomile is worth about 3s. per lb., the very finest selling at still higher prices.

Cultivation.—Chamomile prefers a dry, sandy loam, but stiffish black loam gives the best crop of flowers. The usual method of propagation is from "sets," each old plant being divided in March into ten or twelve portions, which are planted in rows 2½ feet apart, with a distance of 18 inches between the plants in the row. Chamomile may also be grown from seed, but some of the resulting plants will produce the less desirable single flowers. Weeding is done by hand.

The flowers are picked in September, or earlier if the season is dry. Collecting is done by women and children, payment being made by the pound

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Sophro-Lælia Felicia Fowler's variety.—

A small plant with a one-flowered scape of this remarkable novelty was shown, the flower being of fine proportions and great solidity. The colour is well-nigh unique, and may best be described as rich ruby crimson, the shade pervading the whole of the flower. From J. Gurney Fowler, Esq., Tunbridge Wells.

AWARDS OF MERIT.

Odontoglossum Irene (O. thompsoniana × O. Uro-Skinneri).—A plant having a well-flowered raceme of this well-marked form was shown. The body colour of the flower is glowing maroon irregularly intersected and veined white, a slight yellow crest acting as a signal spot. Shown by Messrs. Charlesworth and Co., Hayward's Heath.

Cattleya Neleus var. Sunspot (C.

Iris × C. Ophir).—The rich golden yellow of the widely winged sepals and petals and purplish crimson lip of this handsome variety, while affording a fine contrast, are enhanced in decorative value by the imposing character of the variety. The plant bore a three-flowered scape. Exhibited by Mr. F. Menteith Ogilvie, Oxford.

Cypripedium Nivana (C. Harefield Hall × C. nitens).—There is much, both in the imposing character of the variety as a whole and the handsome dorsal sepal in particular, to suggest the influence of the first-named parent. The pouch is of bronzy yellow hue. A vigorous grower. Exhibited by Messrs. Charlesworth and Co., Hayward's Heath.

Cattleya Astron.—An award of merit for this variety was confirmed. We were unable to locate the plant. From Baron Bruno Schröder, Englefield Green.

Polystichum angulare divisilobum plumosum densum superbum.—It is unfortunate that a gloriously beautiful or handsome plant should have such a millstone about its neck as the above. In some

measure the names are descriptive, hence it would be superfluous if we enlarged upon them (see illustration). From Mr. Amos Perry, Enfield.

Lapageria alba delicata.—This would appear to be a seedling variety between the rose and the white coloured sorts, the pale flesh pink colouring being beautiful in the extreme. Shown by Elizabeth Lady Lawrence, Burford, near Dorking.

Chrysanthemum Mrs. J. Gibson.—A large exhibition Japanese variety having drooping petals coloured pink and freckled with white.

Chrysanthemum Captain Fox.—A large exhibition Japanese variety of the reflexed type. The colour is maroon crimson with pale golden reverse.

Chrysanthemum La Negresse.—A decorative reflexed variety of rich crimson tone. The flower-heads are well supported on short, sturdy peduncles. These three varieties were shown by Messrs. W. Wells, Limited, Merstham, Redhill, Surrey.

The whole of the above-mentioned novelties were shown before the Royal Horticultural Society on the 3rd inst., when the awards were made.

A BEAUTIFUL NEW VARIETY OF THE BRITISH FERN POLYSTICHUM ANGULARE. (See text.)

and the leaves may be gathered any time before the annual portions of the plant begin to fade.

In the English root seasonal variation in alkaloidal content is said to be very small. Atmospheric conditions appear to have a marked influence, the highest percentage of alkaloid being yielded in plants grown in sunny and dry seasons.

CHAMOMILE (ANTHEMIS NOBILIS, L.).

Prospects.—The demand for Chamomile flowers, though slowly decreasing, is a steady and considerable one. Belgium is the chief grower, and on the outbreak of war the price rose from 55s. to 80s. per cwt. for fair average quality. By the end of August 120s. was asked for last year's Belgian flowers, best quality being 140s. per cwt. The new Belgian crop due in September can hardly have been fully collected, so that a demand will exist for English Chamomile, which is normally practically all used for distillation of oil. It will

(up to 1½d.). Rapid drying is necessary if the flowers are to retain their purity of colour, the flowers being laid on canvas trays in a heated drying closet. From 5lb. to 6lb. of fresh flowers yield 1lb. of dry flowers; the yield of dry flowers is about 4cwt. per acre. They are sorted and graded according to colour. A fairly good product would probably be secured if the flowers were picked as they came in bright weather, which is the best time for drying, this being done in the open or in well-ventilated sheds in as thin layers as possible.

(To be continued.)

PLANTING BULBS.

WE would urge all our readers who are contemplating the planting of bulbs to get the work done as soon as possible. Although many kinds can be successfully planted later, there is no doubt that the best results are obtained from those consigned to the earth earlier. Better bulbs are also obtainable now than in a few weeks' time.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Ripe Grapes.—Vineries in which ripe Grapes are hanging should be kept at a very even temperature and the atmosphere quite dry; 45° is quite high enough. As soon as the foliage drops, the bunches may be cut and placed in the Grape-room, where they will keep quite as well as if left on the Vines. Very careful attention will be necessary through the winter in order to keep the berries from damping, and as soon as one decaying berry is noticed, it must be removed. Careful ventilation is of the greatest importance, especially in damp, dull weather.

Plants Under Glass.

Ferns.—During dull winter weather these plants should be frequently overhauled and all decaying fronds removed. Give as much space as possible between the plants in order to harden and prepare them for house decoration in the winter. A close, humid atmosphere must be avoided. A little soot-water may be applied in order to give colour to the fronds and rid the pots of worms.

Crotons.—Examine these plants carefully, and if mealy bug is present, some approved insecticide should be applied to destroy it. All broad-leaved varieties may be carefully sponged, but the narrow and curly leaved varieties ought to be cleaned by spraying, as it is difficult to use the sponge effectually without injury to the foliage. These should afterwards be syringed with clear soft water, the plants being carefully placed on their sides while this is being done. Crotons will benefit by full exposure to the light throughout the winter months.

The Forcing-House.—Where cut flowers are in demand at Christmas, preparations should be made at once by placing a good number of plants in gentle heat now and allowing them to develop gradually. Narcissi in variety are among the most useful; but these require to be brought along very carefully and without strong heat, or many of them may fail to flower. Early Tulips should also be brought on very steadily and in subdued light. Water freely as soon as the pots are well filled with roots. Lilacs are always welcome, and are easily forced providing they are not subjected to very strong heat at first. These may be potted at once and placed in heat as it becomes necessary to meet the demand for cut flowers.

The Flower Garden.

Spring Bedding.—This should be finished with as little delay as possible, so that the plants may have time to make fresh roots before sharp frost sets in. Beds which were planted early will benefit by hoeing. Keep them quite free from decayed leaves, let the edgings be trimmed, and keep the surrounding grass swept so that the place may present a clean and tidy appearance.

Plants in Pits.—Hollyhocks, Pentstemons and various plants in pits or frames which are intended for spring planting should be freely ventilated during mild weather. As soon as they are established in the pits, the lights may be removed on every favourable occasion. Pinch the tops of the most forward plants in order to keep them stocky.

Humea elegans.—These plants are quite safe in a cold pit until frost sets in, when they ought to be removed to some structure where frost can be excluded. Water with great care during the winter months. Under cool treatment very little water will be necessary, but it should be remembered that if once allowed to become too dry at the roots, serious injury will be the result.

The Rock Garden.—It often happens that the roots of some of the stronger-growing subjects penetrate the space allotted to more tender, shy-rooting plants. In such cases it is necessary to remove such roots as far as possible, and replace the soil which has become exhausted with new material. While this work is being done, the special proclivities of the various plants for certain kinds of compost ought to be considered, and

separate mixtures, each containing its special item, made up and applied as it becomes necessary.

The Hardy Fruit Garden.

Morello Cherries.—The pruning of these trees should be taken in hand at once. Let the young wood be judiciously thinned and trained in the same manner as a Peach tree, allowing at least 4 inches between the young fruiting branches. In order to keep the trees well furnished with fruiting wood, a number of the old branches must be removed each year, and this is best accomplished before the trees are removed from the wall. When pruning is finished, the trees should be carefully cleansed with some approved insecticide. These trees are generally grown on a north wall; consequently the training should be accomplished while mild weather lasts.

The Kitchen Garden.

Globe Artichokes.—Before sharp frost sets in, some protection should be placed round the stems of these plants, taking care to leave the crowns open, or damping may set in. The ground between the rows may then be forked up and made to look tidy for the winter.

Asparagus-Beds should be divested of all withered stems, and the surface lightly pricked up in order to remove all young weeds and prepare the beds for a top-dressing of decayed farmyard manure. The alleys ought to be deeply dug, and a quantity of rough manure dug in to enrich the soil for top-dressing in the spring.

Winter Salad.—Lettuces in the open garden which are in an advanced condition should have some protection applied on the approach of frost; or they may be carefully lifted and placed in cold pits, after which a good watering should be given. Batavian Endive may be treated in the same way.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Endive.—To maintain a supply of this fine salad, a few more plants ought to be lifted and planted in a convenient place for blanching. Plants lifted from now onwards should have a good ball of earth attached to the roots, and the work must be carried out as expeditiously as possible.

Rhubarb.—Like all vegetables intended to produce early supplies, the forcing of Rhubarb must be gone into seriously. For Christmas supplies the roots should now be got under cover; that is if they have been exposed as previously advised. At this stage guard against excessive heat, and see that the roots do not receive a check by watering with water many degrees below the growing temperature.

Celery.—Owing to the unusually fine weather experienced in October, Celery continued to grow much later in the season than usual, and the final earthing up was delayed in consequence. As, however, dampness has to be guarded against, no time should be lost in placing the soil up to the stems to the fullest extent.

Peas.—To have an early supply of Peas—that is, during the spring months—a sowing should be made now either in narrow boxes or pots, the latter for preference. There are now to be had from our leading seedsmen some dwarf varieties suitable for this work. Sow in 8-inch pots in a compost of good loam with a little spent Mushroom-bed manure, and stand these in a cold frame until growth commences. Guard against slugs and mice, which do an immense amount of harm just as the young shoots are coming through. The plants must on no account be coddled at any stage of their growth, nor should any attempt be made to force them.

The Flower Garden.

Violets in Frames.—During the dull, sunless days of November these Violets will need looking over frequently, and all the decayed leaves and faded flowers removed. Stir up the soil between the plants with a hand fork. To guard against

slugs, a dusting of soot or lime should be applied between the plants occasionally.

Chrysanthemums.—A number of plants of the border varieties must now be lifted and planted in cold frames to provide cuttings for next year's supplies. It is quite true that Chrysanthemums will stand a good deal of frost, but in cold and wet districts a great many are sure to die out in the winter. Although under the protection of cold frames, the lights should be fully opened during all but very severe weather.

Michaelmas Daisies.—Where these require replanting, the work may be proceeded with now. To keep the stronger-growing varieties within bounds, they need to be replanted every two years. When grown on a border entirely devoted to them, opportunity should be taken to have the ground deeply trenched, adding a liberal supply of good, well-rotted manure as the work proceeds.

Plants Under Glass.

Border Carnations in Baskets.—The system of growing border Carnations in wire baskets for suspending from verandahs and summer-houses is not so generally adopted as it might be, considering its effectiveness. Plants that have not been layered should be used in making up the baskets, and if slightly shaded for a short time will survive the severest weather. We had some plants this season that were 4 feet through, and the flower-stems hung gracefully down about three feet all round. The present is a suitable time to do this work.

Malmaison Carnations.—The earliest potted layers ought now to have almost filled the small pots with roots, and may be potted into 5-inch or 6-inch pots. Later plants can remain in the small pots until January. The soil for this potting should be good loam, a small quantity of leaf-mould, with a little ground charcoal and soot. One watering a few days after potting will probably suffice for some weeks.

Plumbago rosea.—The earliest plants will now be developing their flowers, and may be moved in batches into the flowering house. Each plant should be allowed plenty of space to develop the small side shoots, which will throw some useful flowers after the main stems have finished.

Primula kewensis.—This free-flowering Primula ought now to be coming into bloom, and, in order to draw out the flowers, may be given a little more fire-heat. If kept in too low a temperature, the foliage is inclined to damp badly. Very little artificial manure should be given; a small quantity of liquid manure occasionally will be ample.

The Hardy Fruit Garden.

Apricots.—Owing to these being the earliest fruit trees to come into flower, no time ought to be lost in seeing to any that require to be moved. In transplanting Apricots it is most important that the roots be kept near the surface and the soil made very firm about them. In addition to lime rubble, some gritty matter must be added to the soil. Carefully remove all worn-out branches, and any long spurs may be shortened.

Raspberries.—In making new plantations of these it is wise to select a spot where the soil is fairly moist, and, if possible, in a different aspect from the existing plantation, the reason being that a better succession of fruit can be had. Although a surface-rooting plant, the ground should be deeply dug to prevent the soil becoming stagnant, adding at the same time a liberal allowance of lime rubble. The plants are best planted in rows about five feet apart and 18 inches between the plants.

Fruit Under Glass.

Figs.—Pot trees intended to produce ripe fruit towards the end of April ought now to be placed in a vinery or Peach-house shortly to be started, failing, of course, a pit that could be devoted entirely to them. In the latter a hot-bed could be made up in which to plunge the pots. No attempt should be made to hasten the trees into growth; the starting must be slow and gradual. Damping and syringing must be performed with caution.

JOHN HIGHTATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

PRUNING ORNAMENTAL SHRUBS.

It is doubtful whether any other necessary gardening operation is so little understood, or so seldom properly carried out, as the pruning of ornamental shrubs. In many places, and more particularly gardens of small dimensions, the cutting is carried out indiscriminately and to excess, with the result that the plants never attain the graceful contour and freedom of blossoming that Nature intended. On the other hand, one sometimes finds, even in good gardens where a large staff is kept, shrubberies that are overcrowded and neglected, and far from being the interesting and pleasing feature that a well planted and tended shrub border ought to be.

For the purpose of elucidation we may divide ornamental shrubs, roughly, into three sets, *i.e.*, those that flower in late winter and spring, those that flower in summer and autumn, and those of an evergreen character. The first two sets are of the greatest importance, and, owing to the divergent character of the many kinds embraced, need the exercise of forethought and care.

Shrubs that Flower in Late Winter and Spring.—Of these we find good examples in the Winter Jasmine, Forsythia suspensa or Golden Bell, Spiræa arguta, S. Thunbergii and S. confusa, Winter Sweet (Chimonanthus fragrans), Prunus japonica flore pleno and the Star-flowered Magnolia, M. stellata. Now, it is obvious that as these shrubs produce their blossoms so early in the year, they must be borne on wood that was made the previous autumn; hence to cut away any of this wood before the flowering, *i.e.*, in autumn or winter, would mean a corresponding loss of flowers. For this reason the wise gardener will defer any cutting that may be necessary until after the flowers have faded, but the earlier then it is done the better; for this removal of wood is an inducement to the shrub to produce more growths of a robust character that will, in most instances, flower freely next winter or spring. Although this may be taken as a good general basis on which to work, some knowledge of the shrubs and the conditions under which they are grown will also be necessary. Some shrubs, notably Magnolia stellata, already referred to, are so slow-growing that very little pruning is ever needed, all that is required being an occasional thinning out of old wood. On the other hand, the Golden Bell (Forsythia) or Prunus triloba flore pleno will need their shoots that have flowered cut back close to the old wood if grown in beds or against a wall, but if grown in a border, where large specimens can be accommodated, only a few growths need be treated in this way. Much the same remarks apply to the Winter Jasmine when, on the one hand, it is grown in a confined space and, on the other, where it has almost unlimited room. It will therefore be seen that the pruning of early flowering shrubs calls for the exercise of common sense and knowledge of the habit of the plants and the purpose for which they are grown.

Summer and Autumn Flowering Shrubs.—When we come to these, the remarks as to the exercise of common sense may be applied with equal force. But here the method of pruning will differ considerably. Into this section we may place such shrubs as Buddleia variabilis veitchiana, Tamarix æstivalis, such Spiræas as japonica and Douglasii, Ceanothuses azureus and americanus, Diervillas or Weigelas, and the Spanish and Mount

Etna Brooms. With these shrubs the pruning is usually done in February or March, especially with the Buddleia and Spiræas, which are then cut hard back almost to the old wood. These shrubs produce their best flowers on growths that are made during the current year, and, by pruning severely, the formation of sturdy shoots is induced. Then someone may ask, "Why not prune earlier in the winter?" The reason is this: If the work were done, say, in November or December, the dormant buds that were left would, in all probability, start into growth almost at once, and, consequently, be very liable to damage by cold winds or frost. By leaving the pruning until March, the buds remain quiescent and the danger is to a very considerable extent obviated. The Tamarix mentioned may be pruned in two ways. At Kew it is grown in large lawn beds, and is cut down nearly to the ground level early each spring. On the other hand, if grown in a shrub border and a large plant is desired, less drastic treatment would be called for, a partial shortening back only of the growths being necessary. The Diervillas or Weigelas need different treatment again. Although flowering in summer, the blossoms are mostly on the previous year's wood, and a thinning out of very old growths is all that can be permitted, unless some are shortened to keep them within bounds. The Spanish and Mount Etna Brooms are best left well alone, except to occasionally thin out a few of the old shoots, or to restrict those that are encroaching too much on their neighbours. In doing this, however, do not cut into old wood, otherwise new shoots are not likely to be formed. The Ceanothuses named are cut back almost to the old wood each year, but this must not be taken to apply to such kinds as C. rigidus, C. thyrsiflorus and C. veitchianus, which flower much earlier in the year, and ought, therefore, to be treated as advised for Forsythia. Most of the ornamental flowering shrubs come under one or the other of the types that are named, and, with reasonable care and observation, their pruning ought not to be a matter of great difficulty.

With Evergreen Shrubs the work is of a comparatively simple character. It is usually done for the purpose of admitting light and air to the plants, when a general thinning out of the oldest and worst-looking shoots is called for; or to keep the plants within bounds. In the latter case shortening back of too venturesome growths is demanded, and let it be done with knife or secateurs, not with the garden shears, especially where large-leaved shrubs are being dealt with. Although evergreen shrubs can be pruned at almost any season, March is most generally favoured, because new growth is subsequently very quickly formed, and any branches that may have been laid bare veiled with greenery. H.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

HELICHRYSUM TO NAME (A. B.).—From the piece submitted your plant would appear to be Helichrysum microphyllum, but it would be unsafe to name it unless seen in flower. When that ensues, send us a flower-head and branch for verification. During the winter you had better give the plant frame or cold greenhouse protection.

HARDY PLANTS FOR EXHIBITION (W. P.).—For the first week in September we recommend the following for distinctness and variety. You will note we have given you more than you require, since it is not always well to trust to the exact numbers. Helenium Riverton Gem, H. cupreum, Sedum spectabile atropurpureum, Lobelia Queen Victoria, Aster Amellus Riverslea, A. lævigatus, A. Beauty of Colwall, Statice latifolia, Veronica subsessilis, Anemone japonica alba, A. j. rubra and A. j. Queen Charlotte. If of each of these you plant three specimens to form a group, you should have no difficulty in making a good choice.

TREATMENT OF IRIS STYLOSA (G. Sim.).—This Algerian species requires a well-drained soil of sandy loam to which old mortar or ceiling plaster at the rate of one-third of the whole has been added. Failing these, the next best thing is sandstone broken to the size of a small Orange and in the same proportion. Important cultural items are very firm planting and keeping the rhizomes quite near the surface. The soil firmness tends to moderate grossness of growth and favours a better flowering. A south aspect against a wall should be chosen, and a greenhouse wall for preference. If the soil is of a clayey nature and poorly drained, arrange the plants a few inches above the ordinary level and wedge them about with sandstone blocks. In your district the species, though usually regarded as winter flowering, will not, in all probability, do much in the way of blooming before early spring.

PERENNIALS FOR SHADY GARDEN (G. A. C.).—Doubtless the Apple trees casting so much shade is among the causes of your non-success. This will continue unless the shade can be modified by pruning the trees. You would get the best flowering from such plants as Coreopsis grandiflora, Gaillardia grandiflora, Oriental Poppies in scarlet and other shades, Irises of the Flag section, as aurea, Mrs. Darwin, Dr. Bernice and Mme. Chereau; Pyrethrums J. N. Twerdy, Enchantress, Ne Plus Ultra, James Kelway, Hamlet and Mrs. Bateman Brown; Helenium pumilum, Achillea Ptarmica The Pearl, A. alpina, Campanula Van Houttei, Rudbeckia Newmanii, Anemone japonica rubra, A. alba, A. elegans, Aster Amellus bessarabicus, A. A. Riverslea, A. Sirius, A. lævigatus, A. Novi-Belgii densus, A. ericoides Desire and A. acris. To these might be added Carnations of sorts, hybrid Pentstemons, early flowering Chrysanthemums, and a selection of Daffodils and Darwin Tulips for early flowering. All these had better be obtained in plants and put out during the coming weeks. All flowering climbers prefer sun, and we do not recall any likely to give much success in a "very shady part of the garden." A Rambler Rose may do for a time, and Lady Gay is one of the best. For the greenhouse you had better grow Zonal Pelargoniums, to be had in cuttings or plants now; Perpetual-flowering Carnations, also available now as plants; Heliotropes and Fuchsias, obtainable in the spring as rooted plants; Lillium longiflorum and L. speciosum, available now as dry bulbs; tuberous Begonias in variety, obtainable in February as dry roots; and Primulas and Cinerarias, the seeds of which may be sown in February and March. From cuttings obtained in February next, Chrysanthemums for flowering a year hence may be grown.

GREEN CARPETING PLANTS (Japan).—Just what is likely to succeed and do what you require is very much a question of experiment, and not a little also of cultivation. In a land where "lawn grass is hard to grow" it is obvious that special cultural methods must be resorted to if success is to be attained. In the circumstance we are not surprised to learn that "Pansies were dried up in July," and a much more enduring, more carpeting member of the race like Viola cornuta atropurpurea would, in all probability, do much better. Viola Andwell Gem is another fine carpeting subject, and both are hardy, enduring and freely flowered in England. To ensure

success, however, these should be planted in the autumn—in this country October and November are the best months—and in deeply trenched, heavily manured soil. By these means, and by the free use of cow-manure, valuable rather for its cooling and moisture-retaining attributes than for high manurial properties, these plants are rendered attractive often enough in the poorest and sandiest of soils. Then there is the entire range of the *Aubrietias*, not a few of which luxuriate on old walls and ruins, where little soil and great dryness prevail. There are many varieties, and all are spring flowering. These could be raised from seeds. **Campanula muralis* (portenschlagiana) produces a most refreshing carpet of green, and for a long time is shrouded with pale blue flowers. In similar circumstances to the *Violas* some of the Mossy Saxifrages should be tried, **S. hypnoides*, *S. caespitosa*, *S. geranioides*, *S. Sternbergii* and *S. muscoides* being among the more useful. Other good plants of a carpeting nature are **Silene alpestris*, **Achillea tomentosa*, *A. Wilczekii*, *Herniaria glabra*, *Helxine Solierolii*, *Acena sanguisorbae*, *Veronica prostrata*, **Sedum album* and *S. acre*. A plant of exceptional merit in such cases, though some object to it or account of its Chamomile-like flower-heads, is **Pyrethrum Tchihatchewii*. It will often succeed where grass refuses to grow. These are of prostrate habit, and in the main ornamental in flower also. To ensure success, the value of deep cultivation should be appreciated, as this will assist to reduce watering to a minimum. We have marked by an asterisk those we consider the best in the circumstances named.

TREES AND SHRUBS.

PRUNING TAMARISK (M. E. B.).—You had better leave your Tamarisk until February before you cut it back if it is one of the summer-flowering kinds. If, however, it is *Tamarix tetrandra*, which blooms in May, pruning must be left until the flowers are over. At your altitude the climate may be too cold for the best development, but that you can only find out by experiment. The Willows you mention should be cut hard back in March, just as new growth is commencing.

WHEN TO PRUNE POLYGONUM BALDSCHUANICUM (E. Wolff).—*Polygonum baldschuanicum* may be pruned any time during the winter, but for preference about February. It may be cut back fairly hard if you so desire, for abundance of shoots will be produced next summer from buds on the lower parts of the branches which would otherwise have remained dormant. If you do not wish to prune the plant severely, cut back the wood formed this year to within an eye or two of the base.

PRUNING HIBISCUS (W. H. C.).—Your plants of *Hibiscus syriacus* can be cut back as you desire, but it will be advisable to delay the work until February. The plants may be pruned fairly severely at that time. If you so wish, they can be cut back to within a short distance of the base of the main branches. When the work is done, cover each wound with coal tar, otherwise fungus spores may find an entrance and cause the branches to decay. We shall probably publish a note on the cultivation of this shrub at an early date.

SHRUBS FOR SEASIDE (Plymouth).—The following shrubs are likely to suit your purpose: *Olearia Haastii*, a New Zealand shrub of dense habit, growing 4 feet high and as much across. Leaves evergreen, flowers white, in July. Stands pruning well, and is one of the very best seaside shrubs. *Veronica speciosa*, evergreen, grows 3 feet to 4 feet high and 4 feet to 5 feet through; flowers freely during the autumn and early winter. Likes sea air. *Fuchsia Riccartonii*, usually deciduous, grows 6 feet to 10 feet high and as far through; flowers throughout the summer and stands sea air well. *Arbutus Unedo*, evergreen, 10 feet to 15 feet high and as much in diameter; flowers in the autumn and bears decorative fruit; should be sheltered a little from strong breezes. *Laurustinus*, evergreen, 4 feet to 8 feet high and as far through, will give good results in the position described. *Philadelphus Lemoinei erectus*, a dwarf Mock Orange, 3 feet to 4 feet high, which is likely to give better results than the taller ones. The Lilac is not likely to give very good results in such an exposed place, though it may be tried. Sea Buckthorn (*Hippophaë rhamnoides*), a showy fruiting shrub which thrives well in the vicinity of the sea. Male and female plants must be planted together. Mature plants may be kept to 6 feet or 8 feet high and the same in diameter by pruning. *Berberis Darwinii* is an evergreen which bears orange-coloured flowers in April. It grows from 6 feet to 10 feet high and from 4 feet to 6 feet in diameter. *B. stenophylla* is also an orange-flowered evergreen. Of spreading habit, it grows 8 feet high and as far through. *Tamarix pentandra*, 3 feet high and 2 feet through. It must be cut back in February each year. *Escallonia macrantha*, an evergreen, grows 6 feet to 8 feet high, with a similar diameter. Its red flowers appear in the summer and autumn. *E. exoniensis* is quite as vigorous. It bears white flowers. *E. philippiana* grows about three feet high and the same through. The leaves fall in the autumn and the flowers are white. *Cytisus scoparius andreaeanus* and *C. præcox* are showy Brooms which bloom in May. By cutting them back each year after flowering they form bushy plants 3 feet to 4 feet high. *Ribes sanguineum*, a deciduous early flowering shrub, grows 4 feet to 5 feet high and the same across. *Cistus laurifolius* is a white-flowered evergreen 2 feet to 5 feet high of loose habit. *Hypericum moserianum* is a yellow-flowered tufted plant a foot high. *Erica mediterranea* is of compact growth, 4 feet to 6 feet high and 2 feet to 3 feet through. *Diervilla Abel Carrière* grows 5 feet to 6 feet high and forms a large bush. The

foregoing particulars will give you an idea as to the amount of space required for fully grown plants. The following twelve perennials may be grown: *Papaver orientale*, *Salvia nemorosa*, *Monarda didyma*, *Gypsophila paniculata*, *Delphiniums* in variety, *Phloxes* in variety, *Helianthus* Miss Mellish, *Aster* (Michaelmas Daisy) Climax, *Lychnis chalcedonica*, *Lilium candidum*, *Crambe orientale* and *Heuchera sanguinea*.

CLEMATIS JACKMANNII ON WALL (V. A.).—*Clematis Jackmannii* would succeed in the position named, but it is apt to become very bare at the base. Should you desire to keep the wall well clothed, it would be better to select a plant like *Jasminum nudiflorum*. This plant bears yellow flowers freely during the winter. A free-flowering red Rose will be found in Longworth Rambler. It is a Hybrid Tea, producing its flowers over a long period. Two good Apples to plant as cordons are Cox's Orange Pippin and Charles Ross. The fruit of both kinds will keep until Christmas. The Everlasting Pea can be planted in the position described.

RUSCUS ACULEATUS NOT FRUITING (E. H. K.).—*Ruscus aculeatus* does produce fruits in this country, but as male and female flowers are produced on different plants, it is necessary to plant both sexes together to procure fruits. Propagation is frequently done by division of the clumps; hence it often happens that the plants in certain places are all of one sex, and presumably all your plants are either male or female. If you raise plants from seeds, you are almost sure to procure both sexes. When your old plants flower the next time, take notice whether they are males or females, and procure examples of the opposite sex.

THE GREENHOUSE.

TREATMENT OF RHODODENDRON CUTTING (P. J. T. H.).—Your *Rhododendron* cutting, having now pushed forth numerous fine roots, should be potted in some good peat and sand such as is used for Azaleas, Heaths and similar plants. It is very necessary that the pot be effectually drained. As the roots produced in water are very brittle, particular care must be taken not to damage them when potting. After the plant is potted, a thorough watering should be given through a fine rose, after which it must be returned to the structure in which it has rooted. We do not know the temperature of your hothouse, but when the roots have taken possession of the new soil it must not be kept too warm, as a temperature of 50° to 60° during the winter will be very suitable for it. At the same time, we must congratulate you on striking a *Rhododendron* in this manner, for we have never before met with cuttings of these plants rooted in water alone.

LILY BLOOM FOR INSPECTION (Sister Anne).—The Lily is *Crinum Moorei*, and, when well grown, one of the most ornamental of its class. To do justice it should have greenhouse treatment and a rather liberal fare. It is best grown in rich sandy loam and leaf-mould to which well-decomposed manure has been added. If this latter is not available, a little bone-meal or artificial fertiliser, such as Clay's Fertilizer, at the rate of two small handfuls to half a bushel of soil. In the growing season a dessert-spoonful of the manure sprinkled on the surface soil once a fortnight and watered in would be helpful. At this period, too, the plant should have abundant supplies of water. This is most important. If you have any difficulty in obtaining the soil, any local nurseryman would supply it. The plant is almost evergreen, but well repays a few weeks' rest, and little water is required during the winter months. If you wish to repot it, do so in March next, and use a pot of rather liberal size. Some of the finest examples we have seen were grown in the conservatory, the huge pots immersed half their depth in the water of the fountain basin, the plants revelling in the treatment and flowering grandly.

ROCK GARDEN.

MAZUS REPTANS (E. S. L.).—So far as we can judge from the description given, your plant is the correct one, the question of leaf colour—invariably influenced by soil and other local conditions—notwithstanding. The species, naturally of a carpeting and free habit of growth, would in your district put on a greater vigour, and with good soil might be responsible for the "terrific growth" of which you speak. It is not a plant we should select for the moraine in the ordinary way, as it is much too rampant. Experiences in different localities, however, are so varied that a plant which is rampant in one place may require a good deal of coaxing in another before it can be induced to grow at all. Try firming the soil, both in the tufts and around. This might steady growth and give you an ample reward in flowers another year. Excess of growth is opposed to a good flowering, and a modification of it might bring about the desired result.

ROSE GARDEN.

ROSES DISEASED (Hollyhock).—The Rose Juliet is attacked by the fungus *Actinonema rosæ*, which is often very serious in its attacks upon that variety. Persistent spraying with Bordeaux mixture from May onwards will check it to some extent. Juliet does well in an open position, but flowers on the old wood, and is, therefore, a fit subject for pegging down. Baroness Rothschild is attacked by the Rose rust (*Phragmidium subcorticatum*). All leaves attacked should be collected and burned in the autumn, and spraying with a rose red solution of potassium permanganate will check this disease to some extent. The Hollyhocks are also suffering

from rust, due to the fungus *Puccinia malvacearum*. Raise seedlings and spray them with a rose red solution of potassium permanganate at frequent intervals. *Puccinia ægra*, another rust, is attacking your *Violas*. Cut them down and spray with the permanganate solution mentioned above.

MANURE FOR ROSE (T. H.).—You would probably find cow-manure give you better results than horse-manure for the Rose, and the addition to this of basic slag would undoubtedly be beneficial. You do not say whether your meadow land is light or heavy, so that we cannot advise what artificial manure would be best. We think, if you used a good dressing of basic slag last year, you need not add lime this year, but probably some form of nitrogenous manure will prove of service. Sulphate of ammonia would perhaps be the best for grass land, or steamed bone-flour where the herbage is very poor.

FRUIT GARDEN.

NEW PEACH BORDER (E. L. K.).—You do not say whether the old Peach border is occupied with the roots of the trees still growing in the Peach-house, or whether you are about to plant a new tree or trees in a new border. We presume it is the latter. The following makes an excellent soil compost for a Peach border: From the oldest and best pasture land you have cut some turf in sods 4 inches thick (having first cut off the grass as close as possible). To one cartload of this turfy soil add two barrow-loads of bricks, broken small (the size of a hen's egg), then a good quantity of old mortar rubble (from old ceilings or what not), a quarter of a hundredweight of quarter-inch bones, the same of bone-meal, five pecks of lime, and three pecks of soot. Cut up the turf into pieces the size of a quarter of a brick and mix all well together. If you have not the turf, or cannot procure it, you must use the best soil you have in your garden. The items mentioned may be rather expensive, but if it is borne in mind that a Peach border, when once well made, will remain in good condition for twenty years or more, the cost in the first instance should not be regarded as excessive.

VINES IN A SMALL GREENHOUSE (Peccani).—Yes, November is a good time to plant Vines. Although the border has only recently been made, you ought to plant the new Vines in new turfy loam, the same as is generally used for planting Vines in. We do not mean renew the whole border, but, say, give half a barrow-load to each Vine. Shake all the soil away from the Vine roots, disentangle them carefully, and slightly cut back the points of all the roots (only an inch or so). The new soil should not be wet at the time of planting. Place the soil over and among the roots carefully with the hands in the first instance, pressing it down firmly. When planting is completed, tread the soil firmly down if it is fairly dry. The roots should only be buried 5 inches deep. Give a good watering after planting. This will settle the soil to the roots. Cover the border over with freshly fallen leaves, 10 inches deep when trodden down, and cover with a thin layer of straw (well corded down) to prevent it blowing about. The leaves should not be taken off until the first week in April. Combinations are fine things when it is to the mutual interest of the parties combining; when it is not, then look out for trouble. So it is with Ferns and Vines. Vines to do well must have complete rest in the winter by throwing the ventilators well open night and day, excepting when it is very windy or when there is extreme frost. If you must have Ferns, why do you not have hardy Scotch Ferns instead of foreign ones? When grown in pots under glass, they are quite as beautiful and far more interesting. Two excellent white Grapes to go with Black Hamburgh are Buckland Sweetwater and Lady Hutt.

KITCHEN GARDEN.

CUCUMBER DISEASED (M. Hoad).—The fungus on the Cucumber is *Cladosporium scabiei*. Probably the house has been kept somewhat too close, which is sure to give the conditions which encourage the attack of such fungi.

MISCELLANEOUS.

SOWING GRASS SEED (H. Goodman).—Two pounds of grass seed will be ample for the space of ground you wish to sow. Do not sow the seed until March; then select a suitable day when the soil is moderately dry, and sow the seed evenly over the surface. Rake it in well, roll it lightly, and protect it with old fish-netting or cotton, otherwise sparrows will play havoc with the seed.

USE OF SLOES (Soldier's Widow).—Sloe fruits are sometimes made into jelly, but it is doubtful whether you would find Sloe jelly a financial success with sugar at its present price. You had better experiment with a few, and obtain thereby some idea of the likely cost of gathering and preserving. You will then be able to judge as to whether you are likely to be able to dispose of the jelly to advantage or not. Blackberry jam or jelly would be more likely to prove a financial success.

TO MAKE A DRY TENNIS COURT (Dry Court).—A good dry tennis court can be made of asphalt. Excavate the ground 10 inches deep, place 6 inches of rough broken bricks at the bottom, on that 3 inches of coarse tarred macadam, then finish with an inch of fine asphalt. Or the bed may be filled to within 3 inches of the surface with bricks and clinkers, and be finished off with fine marl or burnt ballast. You would be well advised to

visit some recreation ground where such courts exist, and obtain a little information from the superintendent before you commence your court.

WHITE FLIES FOR INSPECTION (J. P.).—The flies attacking your plants are called white flies, and are allied to both scale insects and aphides. They are exceedingly troublesome pests, and to destroy them the house requires to be fumigated three or four times within ten days. Fumigants, unfortunately, do not destroy the eggs, and some of the scale-like young ones also escape. If you can combine fumigation with the dipping of the plant in the soft soap sulphur dip we have frequently recommended, it will be a considerable help.

FURNISHING A GARDEN (Frank Shearn).—If the bank is small, *Hypericum calycinum* would do; if of moderate size or depth, say, 3 feet to 4 feet, *Cotoneaster microphylla*; and if 5 feet or 6 feet deep, a *wichuraiana* Rose. Either of the last two would trail well; the former could be planted thinly over all. For the wall you cannot do better than plant the Ivies known as *Hedera Helix palmata* and *H. h. p. aurea* in mixture. If these are to quickly cover it, a number of small and young plants should be put out in a well-prepared trench, and not a few extra large old ones, which take more time. If you require flowering trees for the sides of the entrance, plant Paul's Double Scarlet Thorn; if an evergreen, *Cupressus lawsoniana aurea*. In all probability the latter would be best, because of the space apparently at disposal. The Thorn is very beautiful, but should not be nearer than 6 feet to the gateposts. *Rosa rugosa* and its white variety would make a good hedge if there is room for it to develop. Some good Roses as standards are *Caroline Testout*, *Prince de Bulgarie*, *General Jacqueminot*, *William Allen Richardson*, *Viscountess Folkestone*, *Star of Waltham*, *Ulrich Brunner*, *Rev. D. R. Williamson*, *Mme. Abel Chatenay*, *Lyon Rose*, *Killarney* and *Lady Hillingdon*. For a weeping Rose try *Excelsa* or *Minnehaha*. Lawn grass may be sown until mid-October in your locality. Of bulbous plants, Tulips in bedding, Cottage, May-flowering, Parrot and Darwin varieties would afford a display for nearly two months; while Daffodils, *Muscari*, *Fritillaries*, *Squills* and *Chionodoxas* would do the same. Write to some of the dealers advertising in our columns, all of whom make up collections of these things.

NAMES OF PLANTS.—*Cork*.—1, *Alyssum maritimum*; 2, *Hypericum reptans*; 3, *Gazania* species, specimen too scrappy to identify; 4, *Sedum spurium*; 5, *Campanula linifolia*.—*George Neil*.—*Nerine coruscans* major.

NAMES OF FRUIT.—*Mrs. Cumberland*.—1, *Bramley's Seedling*; 2, *Cox's Pomona*; 3, *Duchess of Oldenburg*; 4, *King of the Pippins*, dessert variety; 5, decayed; 6, *Glou Morceau*, dessert variety; 7, *Bellissime d'Hiver*, cooking variety; 8, *Marie Louise d'Uccle*, dessert variety. —*Nemo*.—1, *Newton Wonder*; 2, *Bismarck*.—*C. F.*—All the Pears arrived in a pulp. Sound fruit must be sent. Also see rules. —*H. G. G.*—Large Pear, *Beurré Diel*; small Pear, *Durondeau*. —*S. Dakin*.—The fruit is so similar to *Yorkshire Beauty* that it might be the same variety. —*A. D.*—1, *Mère du Ménage*; 2, *King of the Pippins*; 3, *Blenheim Orange*; 4, *Bess Pool*; 5, *Hawthornden*; 6, *Verulam*; 7, *Sugarloaf*; 8, *Kerry Pippin*; 9, *Queen Caroline*; 10, *Beurré Sterckmans*; 11, *Beurré Superfin*; 12, *King of the Pippins*. This is attacked by "bitter-pit."

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

DURING normal times one of the chiefest values of the fortnightly meetings of the above-named society is the object-lessons afforded of the variety obtaining in gardens as the season advances. On the last occasion the fruit-growers were to the front, while at the meeting held on the 3rd inst. the flower-growers held the field. Naturally, the *Chrysanthemum* was strongly in evidence, and while we have seen greater numbers, we have rarely seen finer quality or better displayed flowers. For one collection of these a gold medal was awarded, a silver-gilt Flora medal being awarded in two other instances. An exceptional exhibit for a November meeting was that of Dahlias from Mark's Tey, the flowers fresh and good. Of much merit, too, was the hardy Fern collection from Enfield. Orchids and fruit were but sparsely shown. The Orchid committee granted awards to four, and the floral committee to five, novelties.

ORCHID COMMITTEE.

Present: J. Gurney Fowler, Esq. (chairman), and Sir Jeremiah Colman, Sir Harry J. Veitch, Messrs. J. O'Brien, F. Monteith Ogilvie, T. Armstrong, Walter Cobb, J. Cypher, J. Charlesworth, J. R. Shill, S. W. Flory, W. P. Bound, Arthur Dye, H. G. Alexander, W. H. White, E. H. Davidson, W. Bolton, Gurney Wilson and de B. Crawshaw.

Only one or two small Orchid groups were staged at this meeting, though they contained not a few choice things. In that from Messrs. Sander and Sons, St. Albans, *Coleogyne mooreana* was prominent, the erect, foot-high raceme of chaste white, yellow-crested flowers showing to considerable advantage. In leaf growth and carriage it is quite distinct from the better-known *C. cristata*, which flowers in midwinter. *C. Brunnea* is an interesting species of the same genus, having short pendent racemes of yellowish green flowers. *Odontoglossum perculum* × *gandavense* has very dark-coloured flowers. *Cattleya Fabia alba*, C. Mrs. Pitt and *C. acis* (rich orange sepals and petals and reddish lip) were all noted in the group.

Messrs. Charlesworth and Co., Hayward's Heath, had a few particularly choice specimens, as *Odontioda Madeline*, *Cattleya Fabia alba* (fine variety), *Odontoglossum crispum*,

O. Areworth (of dark chocolate colour), *Lælio-Cattleya Neleus* (yellow, with crimson-purple lip), *L.-C. Thyone* (yellow sepals and handsome crimson-brown, much-reticulated lip) and the ever-welcome, pure white-flowered *Dendrobium Dearingi*, which is indispensable to any collection at this time. Some of the more important novelties certificated at this meeting were also in this group. (For these see "New and Rare Plants," page 558.)

Mr. E. V. Low, Hayward's Heath, staged half a dozen distinct varieties of *Cattleya labiata*, viz., *Daphne*, *La Vièrge*, *R. J. Measures*, *W. R. Lee*, *Pride of Southgate* and *Mrs. E. Ashworth*, the little group of well-flowered specimens making a goodly show.

FRUIT AND VEGETABLE COMMITTEE.

Present: A. H. Pearson, Esq. (chairman), and Messrs. J. Cheal, E. Beckett, A. R. Allan, H. Markham, H. J. Wright, E. A. Bunyard, W. Poupart, A. Bullock, W. E. Humphreys, A. Grubb, A. W. Metcalfe and Owen Thomas.

From Messrs. W. Seabrook and Sons, Chelmsford, came a collection of thirty-eight dishes of fruit, the whole, save four varieties of Pears, being Apples, of excellent quality and finish. They represented much the same type of excellence, indeed, as was seen in at least two collections at the previous meeting. *Blenheim Orange*, *Cox's Orange Pippin*, *The Queen*, *Allington Pippin*, *King of Pippins*, *Bramley's Seedling*, *Lane's Prince Albert*, *Newton Wonder*, *Warner's King*, *Beauty of Kent*, *Emperor Alexander*, *Peasgood's Nonsuch* and *Royal Jubilee* were among the best sorts of Apples; while the Pears *Emile d'Heyst*, *Catillac* and *Uvedale's St. Germain* were all very fine. *Silver Knightian* medal.

From Bedfords, Havering, Romford, Sir Montague Turner (gardener, Mr. A. Humphreys) sent a small collection of high-class fruits, which included *Black Alicante* Grapes, Apples, Pears and a dish of Guavas. The dishes of Pears of *Emile d'Heyst*, *Durondeau*, *Pitmaston* *Duchess* and *Marie Louise* were particularly handsome-looking examples and well finished; while such Apples as *Cox's Orange Pippin*, *Ribston Pippin*, *King of Pippins*, *Peasgood's Nonsuch*, *Allington Pippin* and *Christmas Pearmain* also claimed attention. *Silver Banksian* medal.

Bunches of the outdoor Grape *Reine Olga de Wurtemberg* were sent by Mrs. Watt Black, Edenbridge, and for the purpose named the variety is one of the more useful sorts.

Dishes of four varieties of Quince, viz., *Champion*, *Portugal*, *Borgeant* and *Pear-shaped*, were sent from the Society's gardens at Wisley. The fruits were of large size.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. E. A. Bowles, J. Green, G. Reuthe, R. Hooper Pearson, J. T. Bennett-Poë, W. J. Bean, J. Hudson, J. F. McLeod, J. W. Moorman, C. R. Fielder, F. W. Harvey, W. Howe, T. Stevenson, J. Jennings, W. Bain, J. Dickson, C. Dixon, H. J. Jones, C. E. Shea, C. E. Pearson, W. Cuthbertson, W. P. Thomson, E. H. Jenkins, G. Paul and W. H. Page.

Messrs. Dobbie and Co., Edinburgh, staged some three dozen vases of *Collarette Dahlias*, as fine in quality, almost certainly as rich and varied in colour, as we are wont to see in September. The exhibit in itself was evidence of the exceptionally mild weather and the immunity from frost experienced in certain districts, while as a display of colour the group was welcome indeed in November. *Doon* (rich orange scarlet), *Purity* (white), *Balmoral* (cerise), *Prince of Orange*, *Cloch* (mauve with creamy inner florets, a most charming thing), *Diadem* (rose cerise) and *Deveron* (deep rose) cerise with white inner florets) were among the best and showiest in a particularly good lot.

Messrs. Rasmussen and Crone, Woodbine Nursery, Wanstead, N.E., showed a capital group of *Begonia Gloire de Lorraine*, together with plants of *Clibran's Pink* and *The Gem*. All the plants were well-grown, compact examples.

Messrs. Barr and Sons, Covent Garden, W.C., displayed a superb lot of *Nerines*. Over three dozen vases of these indispensable greenhouse flowers were staged. The collection embraced many fine examples of *Epic* (rose), *Lady Clementine Mitford* (flesh pink), *Lady Mary Shelley* (delicate flesh), *Flashlight* (rich scarlet), *Miss Carrington* (rose, shaded white at the edges) and *Striped Beauty*. In addition, *Helleborus niger altifolius*, the *Gladwyn Iris* (*I. foetidissima*), of which a superb lot of fruiting pods were shown, and an assortment of *Crocus* species were also on view. Of these, *ochroleucus*, *Hadriaticus*, *sandersianus* and *chrysobolonicus* are all white-flowered and very charming. *Kniphofia aloides glaucescens*, *Iris stylosa* and *Violet La France* were also shown.

The Misses Hopkins, Shepperton-on-Thames, had a small exhibit of alpine, among which were *Sedums*, *Dianthus deltoides*, *Gentiana acaulis*, *Polycnemum vacciniifolium*, *Viola Bowles* Black and others of miniature growth.

Messrs. H. B. May and Sons, Edmonton, displayed a table of winter-flowering *Begonias*, as *Exquisite*, *Mrs. Heal*, *Optima*, *Winter Cheer*, *Glory of Cincinnati* and *Gloire de Lorraine*, all of which were set in group form. *Statice profusa* (good in colour and distinct), *Hydrangea Mme. E. Moulière* (white), and a well-flowered batch of *Cyclamens* were all included, with Ferns, in an interesting exhibit.

Mr. J. J. Kettle, Corfe Mullen, near Wimborne, Dorset, showed some three dozen vases of *Violets*, chiefly of the varieties *La France* and *Princess of Wales*. The flowers were of fine size, and with giant stems displayed themselves to advantage. They were an admirable lot.

Mr. G. Reuthe, Keston, Kent, showed a goodly grouping of *Aster Tradescantii* (white) and a large array of *Nerines*, among which *N. flexuosa alba*, *N. cornucans major*, *N. Nellie Reuthe* (rose) and *N. Kitty* were distinct. *Crocus*

marathonisius (very fine white), *C. longifolius*, *C. media* (one of the best dark-flowered sorts), *Pernettyas* of sorts and a variety of alpine were also on view.

Messrs. Stuart Low and Co., Enfield, showed winter-flowering *Begonias*, as *The Gem*, *Optima*, *Emita*, *Mrs. Heal*, *Exquisite* and other notable sorts.

Messrs. Stuart Low and Co., Enfield, had a superb lot of *Carnations*, showing amply filled vases of *Princess Dagmar* (crimson), *Gorgeous*, *Philadelphia* (pink), *Mrs. Mackay Edgar* (a fine seedling from May Day), *Satin Robe*, *Mary Allwood* and *Mrs. C. F. Raphael*.

Mr. Clarence Elliott, Stevenage, showed a charming lot of *Gentian* flowers, together with pot-grown examples of *Crocus pulchellus*, *C. sativus*, *Potentilla willmottiana* and a variety of other alpine.

Mr. L. R. Russell, Richmond, displayed a floor group of *Aucubas*, *Crataegus*, *Symphoricarpos mollis*, *Ivies*, *Bamboos* and other plants in variety.

E. G. Mocatta, Esq., Woburn Place, Addlestone (gardener, Mr. T. Stevenson), was awarded a gold medal for a superbly arranged group of *Chrysanthemums*, which embraced single, decorative and exhibition sorts. The bold, handsome vases of flowers, ornamented by *Osmunda* fronds and occasionally interspersed by *Crotons*, *Aralias* and like plants, were of a most imposing character, and evoked much praise. *Cranford Yellow*, *H. W. Thorpe* (white), *Source d'Or*, *Virginia* (white) and *Mrs. E. Tickle* (pink) were all good. *Celia* (yellow), *Mensa* (white), *Ceddie Mason* (crimson), *Charles Kingsley* (yellow), *Bronze Pagram*, *White Beauty* and *Mrs. Loo Thomson* (primrose) are all singles, and constituted a front line to this excellent group.

Messrs. J. Peed and Sons, West Norwood, S.E., had an extensive group of *Chrysanthemums*, using a big line of *Stuart Smith* (white, semi-double) in the background. *Charles Kingsley* (yellow), *Buttercup*, *Geoffrey Peed* and *Fred Humphries* (red) are singles chiefly, and of good decorative merit.

Messrs. H. J. Jones, Limited, Lewisham, S.E., set up a magnificent collection of *Chrysanthemums*, the back line of vases, composed in each case of about a score of giant blooms, all of exhibition standard, evoking much praise. There were fifteen of these vases; hence the imposing character of the group is easily gauged. *Bob Pulling* (yellow), *Mrs. E. Tickle* (pink), *Mrs. R. C. Pulling* (yellow), *J. Surry* (crimson), *Mrs. Wiseman* (white, incurved), *R. Crocker* (pink) and *Romance* (golden) were all of exceptional merit. The front line was made up of singles naturally arranged in bowls, and in this way constituted a good setting to a very fine lot.

Messrs. Allwood Brothers, Hayward's Heath, showed some excellent *Carnations*, *Carola*, *Princess Dagmar* (both crimson), *Salmon Enchantress*, *Wivelsfield White*, *Mary Allwood*, *Gorgeous* and *Champion* being a few of the best in a particularly nice, fresh-looking lot.

Messrs. Waterer, Sons and Crisp, Limited, Bagshot, Surrey, showed herbaceous flowers, as *Michaelmas Daisies*, *Eryngiums*, border *Chrysanthemums*, *Iris stylosa*, *Salvia Grahamii* (scarlet), *Iris alata*, *Sedum pilosum*, *Kniphofia Nelsoni* and other useful plants.

Mr. C. Engelmann, Saffron Walden, showed *Carnations* *Enchantress Supreme*, *White Wonder*, *Gorgeous*, *Lady Northcliffe*, *Lady Meyer* and others, all of fine quality.

The Misses Price and Fyfe, Lee, S.E., displayed *Chrysanthemums* in variety, *Mrs. Andrew Walker* (deep bronze) being very fine. *Carnations* *Enchantress Supreme*, *Mikado*, *Kenneth* (both fancies) and *Mrs. Ward* (cerise) were also from the same source.

Mr. W. Wells, jun., Merstham, had quite a show of *Gentiana acaulis* with *Erica mediterranea hybrida* and other plants.

Messrs. Wells, Merstham, had a good show of *Chrysanthemums*, single and double. *Ideality* (white, single), *Ceddie Mason* (crimson, single) and *Caterham Bronze* (single) were very good. *Queen Mary* (giant white), *Thomas Beeson* (bronze) and *Mrs. R. Luxford* (bronze) are large-flowered sorts. *Petite Jeanne* is a pure white of useful size for cutting.

Messrs. H. Canneil and Sons, Eynsford, Kent, had an admirable lot of *Zonal Pelargoniums*. *Queen of Italy* (pink), *Sir Thomas Hanbury* (deep crimson), *Vesta*, *Hall Caine*, *The Sirdar*, *Maxime Kovalevsky* (all brilliantly flowered sorts) were very fine. *Mrs. J. Ward* is a particularly large-flowered variety of salmon colour.

Messrs. J. Cheal and Sons, Crawley, showed cut shrubs, among which were five species of *Symphoricarpos*, viz., *racemosus*, *montanus* (pink fruited), *Heyeri* (small creamy-coloured fruits), *vulgaris* (red) and *occidentalis* (creamy fruited and of distinct leafage). *Ceanothuses*, *Acers*, *Pernettyas*, *Veronicas* and *Baccharis balimifolius* were also noted.

Mr. Norman Davis, Framfield, Sussex, had an excellent table of *Chrysanthemums*, single, decorative and others. *William Turner* (large-flowered white), *Glorious* (yellow), *Mensa* (white), *Mrs. Loo Thomson* (primrose) and *Excelsior* (bronze) were singles of high merit. *Dandy* (reddish), *Mrs. G. Drabble* (white), *F. A. Wheeler* (bronze) and *His Majesty* (crimson), all large-flowered sorts, were others of note.

Mr. Amos Perry, Enfield, staged a very remarkable and comprehensive collection of *Polystichums*, a much-valued genus of hardy evergreen Ferns which, during the late summer and autumn months, are often at their best. There were some four or five dozen sorts, chiefly, however, of the variations of *P. angulare*. Of these, the very handsome *P. a. divisilobum plumosum densum superbum* (see page 558) was the most conspicuous. It is a plant of high ornament and distinction. Other distinct sorts included *P. a. d. densum*, *P. a. d. plumosum densum*, *P. a. d. robustum*, *P. a. grandiceps*, *P. a. frondosum*, *P. a. f. decompositum* (with neatly cut pinnules), *P. Lonchitis* (Holly Fern), *P. aerostichoides* and *P. munitum*.

THE GARDEN.

No. 2244.—Vol. LXXVIII.

NOVEMBER 21, 1914.

NOTES OF THE WEEK.

Sir Herbert Maxwell's Lily Articles.—In response to enquiries from a number of readers as to the promised articles on Lilies by Sir Herbert Maxwell, Bart., we are now able to state that these will commence in the first issue of next year. By starting these articles then it will ensure them all appearing in the same volume, which will be more convenient for those who bind their copies than spreading them over two volumes.

A Good Autumn Rose.—When inspecting a large collection of Roses on November 10, we were much interested in a bed of *Corallina*. The plants were as full of flower as one would expect to find them in July, and the quality was but little inferior to what it is earlier in the year. Indeed, many of the blooms would not have disgraced a summer show. On several previous occasions we have noticed how good this Rose has been in autumn. Although classed as a Tea variety, it makes vigorous, erect growth, and the beautiful coral red blooms stand up well on long, stout stems. It was raised by Messrs. William Paul and Sons, and first sent out by them in 1900.

A Little-Known Pyracantha.—The rather rare shrub *Pyracantha crenulata* has been very attractive at Kew during the present autumn by reason of its profusion of bright red berries, comparing well with the better-known *P. coccinea*, or *Cratægus Pyracantha* as it is frequently called. *P. crenulata* is a native of the Himalaya and China, and is a rapid-growing shrub, with rather larger and thinner leaves than the ordinary *Pyracantha*. The white flowers are borne in May, and the bright red berries, which are rather smaller than those of the better-known species, ripen in October. It may be planted in a shrubbery in ordinary garden soil, or may be placed in the open and allowed to develop as an isolated specimen. As a wall plant it may be considered to be of similar use to *P. coccinea*.

A Charming Autumn Crocus.—When at Kew a few days ago we were very charmed with a small bed of *Crocus longiflorus* situated by the Rose pergola. Although the circular bed was barely 2 feet in diameter, there must have been well over a hundred of the beautiful lilac blue flowers. Each of these has a vivid orange stigma, which adds not a little to its attractiveness. This charming

November Crocus is a native of Southern Italy, and deserves to be cultivated wherever a sunny spot can be devoted to it.

A Beautiful Golden Cypress.—Those who wish for a handsome and distinctive-looking evergreen should secure *Cupressus obtusa Crippsii*. This makes a particularly pleasing shrub of columnar form, its rather loosely placed branches avoiding the stiffness that to many is objectionable in a number of other Cupressuses. The foliage is of a pleasing golden shade, mixed with dark green and as an isolated specimen in a lawn bed it would be particularly pleasing.

Erica Cavendishii.—This is one of the few greenhouse Heaths, so much grown in years gone by, that still retains its old-time popularity.

ERICA CAVENDISHII, A BEAUTIFUL GREENHOUSE HEATH WITH GOLDEN FLOWERS.

during the season—that is to say, principally in early summer—delightful specimens, such as are herewith illustrated, are freely brought into Covent Garden Market, grown either in 5-inch or 6-inch pots. A notable feature of *Erica Cavendishii* is the bright yellow colour of its blossoms, in which respect it stands out markedly from all its fellows. It is regarded by our different authorities as of hybrid origin. These greenhouse Heaths are all exceedingly chaste and beautiful; but with very few exceptions they are now seldom seen.

November-Flowering Evergreen Shrub.—Under the several names of *Fatsia japonica*, *Aralia japonica*, *A. Sieboldii* and the Castor Oil Plant, a very valuable Japanese plant is grown extensively in pots for greenhouse and room decoration.

Though a very valuable plant for these purposes, it is as an outdoor subject that its greatest beauty is seen. Particularly happy in the town and suburban garden as a lawn specimen or in the shrubbery border, those who have grown it regard *Fatsia japonica* as one of the most beautiful evergreens for London gardens, further South and in the West. Most attractive at all seasons with its large leathery, shiny green leaves, it is in November, when flowering freely, that we see the full beauty. The flowers are milky white, individually small, but very freely and effectively produced in large branching inflorescences on bushes 4 feet to 8 feet or more in height.

Pear Crossed with Quince.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. J. C. Allgrove of the Langley Nursery showed several fruits of the Pear raised by Mr. John Seden from the Pear *Bergamotte Esperen* crossed with pollen from Portugal Quince (see *Journal of the Royal Horticultural Society*, Vol. XXXIII., pages clxvii. and clxxi). The fruits of this type are essentially Pears, very similar in shape and appearance to *Easter Beurré*, very short-stalked, roundish, and plentifully dotted all over with large dots. The flavour is good and the Pear ripens long before its Pear parent *Bergamotte Esperen*, being fit to eat at the end of October. It will be remembered that the other plant raised from the same fruit was Quince-like in form, and never becomes soft.

A Useful Evergreen Climber.

During spring and summer, when our gardens are full of other flowers, such useful and ornamental foliage plants as *Smilax* are often overlooked. We were recently admiring some white *Chrysanthemums* growing in front of some *Smilax* against a wall, and the effect of them against the dark background was very striking. The *Smilax* may not be perfectly hardy in all parts of the country, but if placed against a wall in well-drained soil and covered with pieces of stone, through which the young *Asparagus*-like shoots are not slow to appear. Should they be cut to the ground during severe weather, they soon sprout up again. *Smilax Cantab.*, *S. laurifolia*, *S. rotundifolia*, *S. excelsa*, *S. aspera*, *S. tannoides* and *S. glauca* are a few of the best.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Nerines.—There were one or two pretty displays of this delightful autumn-flowering plant at the Royal Horticultural Society's show on the 3rd inst., and there is little wonder that each succeeding year sees the Nerine more and more to the fore. Messrs. Barr made a departure by exhibiting cut spikes in vases with fronds of *Adiantum*; but I still think the method of showing the plants in their small pots as grown the more attractive one. Anyone with a little greenhouse space to spare can grow the Nerine, and it is the plant *par excellence* for the intelligent amateur who would like to devote his spare time in the fall of the year to a little hybridising and seedling-raising.—F. H. C.

Saxifraga Fortunei.—I enclose a photograph of *Saxifraga Fortunei*, in case it may be interesting enough to reproduce. It was taken on October 16 last year. This Saxifrage was planted in the autumn of 1909, and is in a position where it only gets late afternoon sun in the winter, though in the summer it has sun nearly all day. This year it again has two spikes of flower, but they are not nearly as tall.—CONSTANCE FAWKES, Bayshill, Cheltenham.

Winter-Flowering Begonias.—In the issue of THE GARDEN for November 7 I expressed regret at the dispersal of Messrs. Veitch's fine collection of these beautiful flowers. There is apparently, however, a successor within the London area; for at the meeting held at the Royal Horticultural Hall on November 3, Messrs. Stuart Low and Co. of Enfield exhibited a group of the best forms. It is to be hoped that the mantle of Messrs. Veitch will descend upon the new-comers in this line, and that Messrs. Low will be as successful as were their predecessors in the production of new varieties.—H. P.

Vitis Thomsoni.—The past hot summer has been followed by fine autumn tints. *Vitis Thomsoni* is now a brilliant red, almost as bright as *Vitis inconstans* (*Ampelopsis Veitchi*), and, strange to say, though growing for many years on this house, it has never before attained the same rich colour. It is the more acceptable now, most of the leaves of the Virginian Creeper and *Ampelopsis Veitchi* having fallen. *Vitis Thomsoni* is also a contrast to other climbers in summer from its very dark green leaves and its graceful habit of growth. Our plant covers a considerable space of wall.—J. H. W. THOMAS.

Moss on Tennis Court.—Your correspondent "G. J." evidently has to deal with a sand court situated in a somewhat damp spot, and consequently the recurrence of moss is not to be prevented by one operation, as is evidenced by the statement that weed-killer has failed. A cheap and effective remedy would be to apply now a dressing of powdered lime, and in a fortnight's time to follow this with a similar dressing of common salt. Soiled salt can be purchased very cheaply for this purpose. Three to four ounces to the square yard will be necessary for each dressing if the mossy growth is dense. A few days after applying the salt the court should be

well swept with a stiff broom. Treated thus, moss will be kept at bay for a considerable time; but as soon as signs of a fresh growth appear, another application is necessary.—HEATHER BELL.

Propagating Perpetual-Flowering Carnations. Seeing that this question has cropped up again through the notes of Mr. Brotherston, I venture to repeat that the commercial grower long since satisfied himself as to the advantage of striking cuttings in January or February rather than in the autumn. If autumn rooting gave better plants, surely the men whose combined cultures must total millions of plants would not adopt spring rooting. In the first place, taking of cuttings in the autumn means so many fewer blooms in the winter from the stock plants. Furthermore, autumn-struck cuttings have to face a period of

SAXIFRAGA FORTUNEI IN MRS. FAWKES' GARDEN AT BAYSHILL, CHELTENHAM.

dull weather and shortening days. It is idle to claim that autumn-struck plants will give a greater crop in a given period, for the commercial man is out for quantity as well as quality. The spring-struck plant commences to crop by early October, often earlier, and if the variety is not addicted to coming in crops, it will never cease blooming until thrown out. On a great commercial grower's showing we know that a January or February struck plant will outyield an autumn-struck one over a given period; and considering the fact that this type of Carnation is never at rest, why advocate a method that entails one winter over and above what is essential in a plant's life-history? I am prepared to agree that late summer-struck cuttings are better for open ground culture and infinitely more easy for the amateur to handle. Incidentally, I might mention that I had on November 1

several first-rate blooms of *Britannia* on plants that have been in a bed for the past eighteen months. This variety is superior to any other Perpetual-flowering Carnation for the open ground, as it does not rot so freely in damp weather.—T. A. W.

Myosotidium nobile from Seed.—The value of seeds as a means of increase is very great—greater, perhaps, than in these days is recognised, when we have become so dependent on plants to name derived from cuttings or similar means of propagation. This sentence will serve as an introduction to what I want to write about *Myosotidium nobile*, a note concerning which you were good enough to publish earlier in the year. I received the plant just twelve months ago, taken up from the garden of the late Miss Patricia Dalrymple, with whom for many long years I had carried on a reciprocal give-and-take in garden and greenhouse plants. This, the last of her gifts, I should have been more than sorry to have lost, and though the plant thrives here and there in Scotland in the more genial parts, I was dubious about trusting it to the mercy of our east winds, notorious for their cutting properties. So I saved all the seeds the plant had matured in the early summer and had them sown directly. Some germinated in a short time, and the seedlings have been appearing a few at a time up till the present. The plants from the first and second batches are in 9-inch and 10-inch pots, with foliage almost as large as that produced by the parent plant. I am now anticipating the appearance of flower-spikes before very long, and anyhow shall have the pleasure of planting a lot of the seedlings in selected positions out of doors. I knew the conditions under which this plant thrives in its native island—loose sandy soil by the seaside—so the seeds were sown in leaf-soil and loam, and the plants have been potted in about equal parts of the same material, only with lumps of turf instead of loam for the larger plants. The compost was only slightly firmed, and the plants are growing in a cool house with abundance of fresh air blowing about them. At Enys I believe the *Myosotidium* borders are regularly dressed with seaweed, but I do not know that this is essential. We have here plenty of flaky leaf-soil, which I hope to utilise when planting. It proves splendid rooting material, is fairly lasting, and retains moisture for a long time once

it is wet, having previously been made very firm.—R. P. BROTHERSTON.

Mildew-Proof Roses.—My experience has taught me that few such varieties exist, and I lay the blame, chiefly, at the door of those who raise our new Roses. The idea to-day seems to be to get a new thing, something fresh, and it is very questionable—judging by the behaviour of many recent varieties—whether the possibility of being mildew-resistant is ever considered. Admitting this, however, there is still much to be said for the varying districts and positions in which Roses are grown. The same varieties are far freer from its onslaught in some places than others. Mildew-proof climbing Roses with us are American Pillar, Blush Rambler, *Félicité Perpétue*, Jersey Beauty and Psyche. Small-flowered Roses—Jessie, Mrs. Cutbush and Orleans.

Other varieties, such as Rosomane N. Thomas, Irish Elegance, Dorothy Page-Roberts, General Macarthur, Mme. Edmée Metz, Lady A. Stanley, Commander J. Gravereaux, Ulrich Brunner and Miss Cynthia Forde, are also practically immune; while La Tosca, Mme. Ravary, Dr. Andry, Marie Baumann, S. M. Rodocanachi, Maman Cochet and Corallina are so very seldom attacked that I do not hesitate to affirm them as being varieties little predisposed to mildew.—C. TURNER, *Highgate*.

— I was much interested in the notes in your last two issues on mildew-proof Roses. I give below a list of Roses which are exceptionally free from mildew in these gardens: Lady Alice Stanley, Reine W. Urban, Dorothy Page-Roberts, Lady Ursula, Lady Pirrie, Margaret, Mrs. C. Allen, M. Paul Lédé, Joseph Hill, Mme. Second Weber, La Tosca, White Caroline Testout, Mrs. W. C. Miller, Edu Meyer, Beauté de Lyon, Mrs. John Laing, Château de Clos Vougeot, Souv. de Marie de Zayas, Gustav Grünerwald, Helen Keller, Marjorie, Grace Molyneux, Mrs. David McKee, Sunburst, Lyon, Richmond, Frau L. Rautenstrauch, Countess of Shaftesbury, Pharisæer, Duchess of Wellington and Caroline Testout. A few of the worst offenders here are Betty, Lady Ashtown, George Dickson, Ethel Malcolm, Theresa, Viscountess Enfield, Killarney, Harry Kirk and British Queen. I may add that the soil is very wet and of a clayey nature.—JOHN HEXTALL, *Dunscar Gardens, Bolton*.

— I was more than ordinarily interested in "Somerset's" letter, page 528 of October 31 issue, on this subject. I have until this year been under the delusion that many varieties were mildew-proof. I am now rather sceptical as to whether there are any entirely so under every climatic condition. This year the only three varieties that showed no trace of this dread fungus were Grüss an Teplitz, Château de Clos Vougeot and Beauté de Lyon. Others not very seriously attacked were General Macarthur, Mrs. Edward Powell, Gustav Grünerwald, Mme. Melanie Soupert, M. Paul Lédé, Marquise de Sinety, Mme. Maurice de Luze, Liberty, Mrs. David McKee, Ulrich Brunner, J. B. Clark, Hugh Dickson and Prime-rose. All the others of our 170 odd varieties were more or less seriously disfigured. The worst probably were Mme. Ravary, Frau Karl Druschki, George Dickson, Mrs. R. G. Sharman Crawford, Mrs. A. R. Waddell, Killarney, Juliet, Mme. Abel Chatenay, Viscountess Folkestone, and York and Lancaster. I never before saw the last named so seriously attacked. Late in the season I noticed the soft points of Dorothy Perkins on arches become quite white with mildew, but Lady Gay on a west wall showed but small traces of the disease. The Scotch Briars kept wonderfully healthy. Like "Somerset," I have no faith in any of the so-called specifics. I tried several this season, and found them as effective as cold water. If raisers cannot produce mildew-proof varieties, can nobody invent a really certain cure?—C. BLAIR, *Preston Gardens, Lidlithgow*.

FORTHCOMING EVENTS.

November 30.—National Chrysanthemum Society's Floral Committee Meeting, Essex Hall, Essex Street, Strand, London, W.C., 4 p.m. The public will be admitted free.

December 1.—Royal Horticultural Society's Exhibition of British-grown Fruit, Royal Horticultural Hall, Vincent Square, Westminster, 2 p.m. to 4.30 p.m.

THE BOG GARDEN AND ITS FORMATION.

OF the many phases of open-air gardening, none, perhaps, is fraught with greater possibilities, and none, certainly, possessed of greater charms, than the bog garden if well and rightly conceived. It is in this type of garden that we see plants grow, flourish and blossom that too frequently are met languishing for the moisture they love in the open border. Indeed, one of the great charms of bog gardening is that the plants thrive and grow apace, and that nothing droops or dies, simply because the subjects are rightly placed and constantly provided with the moisture so essential to their well-being. But in the bog garden, as in all else, there is just the possibility of the strong crowding out the weak—just the possibility that by one false step, made unwittingly, a plant may be introduced that may prove a nuisance for years. Hence, at the outset, there is the same need for discretion and for that close, intimate knowledge of the subjects chosen for the work, of their slow or quick growth as well as their ultimate development, as there is in any other phase of gardening work.

The host of plants benefiting by constant supplies of moisture during a hot season may tempt some to introduce those that intrude their presence in all directions, or that quickly choke or overrun others whose finer attributes render them far more desirable for such a place. Of such as the former many examples might be given, though one, the *Epilobiums*, will suffice for all purposes. Here we have a small group of rapidly increasing plants that appear to grow all the year round, sending out such vigorous stolons or underground shoots or stems which, springing up some distance from the original, soon make their presence felt in their new homes. For such as these, then, welcome as they are in the wild garden, there is no room—there should certainly be no place—in the bog garden we have in mind, and no quarter should be given to the smallest seedling which might appear. Thus it will be seen that, in our opinion, a bog garden should not be a sort of dumping-ground for any and every moisture-loving plant; rather should it be a spot—an adjunct to the garden proper if you will—to be enriched and beautified with the choicer subjects of other climes as well as those of our own land, subjects which, revelling in moisture, know no happier place than the natural bog.

But some may say, very few gardens are possessed of or include a naturally boggy spot; hence, if we would grow such things as delight therein, an artificial substitute must be arranged. In connection with this not infrequent question arises the all-important point as to whether the abode for such plants must be made water-tight. The correct answer depends not a little on the nature of the subsoil. Where a retentive, plastic clay soil exists, a veritable dribble or trickle of water will maintain the soil in a state of semi-saturation, sufficient, indeed, for all purposes. On the other hand, where the subsoil is of sand or gravel, a slight excavation of this will be required to admit of the introduction of well-tempered clay, than which nothing is so good or so natural. A lowering, too, of the ultimate surface soil is desirable in those instances where a light soil obtains, to

admit of the water from the rainfall finding its way into the bed.

In all large gardens in hilly districts, the forming of an artificial bog garden or bed is quite an easy matter. The ideal condition for such is when a fountain basin exists on the terrace lawn, with the overflow tumbling into a rock garden pool a few feet below, and in turn trickling away into the woodland lower down, where it can be used to advantage for the purpose we have in mind. In just these happy circumstances, many years ago I spent much time in adding beauty to a phase of gardening not then common, and where the founder of the garden delighted on occasion to roam. An opening in the wood gave all that was desirable, and with sun and warmth and varying degrees of moisture a large area was furnished with the plants varying from such carpeting subjects as *Anagallis tenella*, *Sibthorpia europæa*, *Linnæa borealis* and *Pratia angulata* to the giant Royal Fern, *Osmunda regalis*, of several feet high and through.

There are also peat-loving and loam-loving plants, handsome Lilies as *pardalinum* and *superbum* that reflect their greatest beauty in the woodland bog garden, while dozens of others, *Primulas*, *Trilliums*, *Sarracenias*, *Parnassias*, *Dodecatheons*, *Cypripediums* in variety, *Saxifraga Hirculus*, Marsh Marigolds, Orchises, *Pinguiculas*, *Droseras* and the like, may all be grown to perfection in a few square feet of bog. There are, of course, *Primulas* such as *P. japonica* and *Saxifragas* such as *peltata* that are not quite suited to the smallest of these bog-beds, unless, indeed, they be given place at the outer margins where the chief supply of moisture enters. Just what is suited to any and every case will, of course, depend entirely upon circumstances. Happily there are plant giants like the *Gunnera*, *Osmunda* and *Spiræa*, together with the miniatures I have already named, that make bog gardening possible in large and small gardens alike, and where the plants of our own marshes and woods may, with others from the higher mountains of Europe and elsewhere, jointly play their part in making this aspect of gardening one of the most fascinating of the year.

E. H. JENKINS.

AUTUMN-FRUITING STRAWBERRIES FOR AMATEURS.

THIS season, in many parts of the country, has been a favourable one for the ripening of late fruits; and, in addition, the plants have made fine crowns and promise well for the future. There are now several distinct autumn-fruiting varieties, and they can be grown at a small cost as regards labour and space, so that they should in the future become better known. Since the advent of the earliest introduction, St. Joseph—raised in France by crossing a true alpine with a garden variety, which furnished us with an entirely new race of autumn fruits—have come the larger St. Antoine de Padoue, of which St. Joseph is one of the parents and the popular Royal Sovereign the other; and Laxton's Perpetual, in which also the popular St. Joseph has been used as one parent and the large Monarch or summer fruiter the other, and it is certainly a fine fruit of the autumn type, richer than St. Antoine de Padoue and the shape more after Monarch, with a deep red colour and

good flavour. Doubtless the varieties before noted are only the forerunners of a distinct type of autumn-fruiting Strawberries.

Of other alpine forms there are some good varieties, such as Alpine White or the Blanc Ameliore of the French; Bergeri, a rich crimson, medium-sized fruit and a very free bearer; and one that is a great favourite at Gunnersbury House called The Gunnersbury, a large, long fruit, deep red and very prolific.

Of true perpetual types, a year or two ago I noted a fine lot of Alphonse XIII., a round, white-fleshed fruit, rich and good; but white fruits do not find much favour in this country, and I prefer the larger Louis Gauthier, a pale white with pinkish shade and of excellent flavour.

In the culture of these Strawberries the work, to yield a late supply, should be varied. For use in August and September I prefer an open, sunny quarter, and if the runners are planted in well-cultivated soil enriched with manure, they will give an early crop. For instance, runners planted in the autumn will give a full crop in August and September of the following year. I have planted in April and had a good autumn supply. As I have previously noted, the perpetuals are mostly of compact habit; but there is no gain in crowding, as the fruit is produced at a season when the days are shortening and the sun less powerful. It is an advantage to give room, so that the fruits are freely exposed. If planted in rows 18 inches apart and 12 inches is allowed between the plants, this will suffice, but I prefer more room between the plants in the row.

Runners are produced freely, and these may be detached from the plants and put into 3-inch pots when ready, and when strong enough placed in 5-inch pots for November supplies, removing the flowers as they show till the end of August. I prefer to plunge the pots, as it saves watering. These plants, if placed on shelves early in October, will give the latest fruits, and they will take liberal supplies of food. Another plan, and one that will meet with more general approval, is to pot up strong runners in June or July direct into the fruiting pots and grow on a cool coal-ash base through the summer, keeping them clear of runners and flowers till the end of August, or even later for a November supply. When housed the plants require very little warmth to set and swell up their trusses; 50° to 60° is ample, and they do well on shelves. If grown in a frame, moisture must be given sparingly when the weather is sunless, and the plants should be near the light and ventilated freely in fine weather. Plants may be placed in frames in October and merely sheltered from heavy rains, transferring them to the shelves as required; by this means fruit may be had in December.

In the open, runners planted in autumn fruit early in August, and spring runners give a later crop, but here the same procedure is required as regards removing the earlier blossoms to get the fruits at the season required. G. W.

PEAR CHARLES ERNEST.

ALTHOUGH this Pear is not yet widely known, it is an excellent dessert variety, and fruits well grown in almost any form. In the accompanying illustration it is depicted as a pyramid, a type of tree that is admirably adapted for small gardens.

A YOUNG PYRAMID TREE OF PEAR CHARLES ERNEST. THIS IS A GOOD DESSERT VARIETY AND NOW IS THE TIME TO PLANT.

In appearance the fruit resembles that of Souvenir du Congrès; the flesh is snow white, juicy and melting, and the flavour refreshing and excellent. It is in season during November and December. When shown before the Royal Horticultural Society in 1900, this Pear received a first-class certificate, and experience gained since then proves that the honour was well deserved. As the planting season is now with us, those who are desirous of adding to their existing varieties should certainly give Charles Ernest a place. It was raised by M. Ernest Baltet of Troyes, France, and first put into commerce by him in 1879.

GARDENS OF TO-DAY.

BOSAHAN, CORNWALL.

AMONG the many beautiful and interesting gardens to be found in the county of Cornwall, few possess greater charm or wealth of rare vegetation than Bosahan, or the House on the Haven. The present mansion, which is the seat of Sir Arthur Vivian, is quite modern, having been built by himself and Lady Jane Vivian about thirty years ago on the site of an old and historic residence, and it would be difficult to find a situation that is at once so secluded and yet commands such a wonderful view of the English Channel. Bosahan is situated on a narrow point of rocky land that stretches well out into the Channel, and to reach it the visitor either has to cross that arm of the sea known as Helford Passage or take a long overland route *via* Helston. It is not our intention, however, to dwell upon the natural beauties to be seen in this corner of our westernmost county, but to give a few details of the many interesting features to be found in the gardens that surround the mansion and extend for a considerable distance into delightfully wooded vales beyond.

Near the main entrance to the house the first object that attracts and holds the interest of the visitor is a magnificent hedge of *Fuchsia Riccartonii* about twelve feet high and half that in diameter, while many of the plants possess stems as thick as one's wrist. Near by is another magnificent hedge of *Escallonia macrantha*, flourishing as only this plant does in such favoured localities. The walls of Bosahan are clothed with a fine assortment of rambling plants, and we were particularly interested in wonderful examples of *Cassia corymbosa*, *Bougainvillea glabra*, *Sollya heterophylla*, *Tibouchina macrantha*, *Solanum jasminoides*, *Lageria rosea* and *Benthamia fragifera* that were all in perfect health on the wall facing south. On the south-west front we were interested to find a fine specimen of *Rose Mme. Lambard* that

had attained a height of 30 feet, and which at the time of our visit (early April) was in full flower. *Cestrum purpurea*, *Lonicera Hildebrandtii* and a fine *Pittosporum* were other plants that called for special mention on this wall.

The Fern and Goodah Glens.—To the visitor from less favoured localities the Tree Ferns at Bosahan are one of the most interesting features. These are grown in two charming glens, through the whole course of which a gentle stream of crystal water wends its musical way to the sea. The trees in these glens are mostly tall Oaks with moss-grown stems, which stand like sentinels

over the host of choice Rhododendrons, Bamboos, Dracænas and scores of *Chamærops excelsa*. These, in the partly subdued light, impart quite a subtropical appearance to the glens, while ever and anon the visitor comes face to face with magnificent colonies of Tree Ferns. Bordering the sea and leading from one glen into another of similar size is a charming woodland walk, overhung by Hazel boughs and Hawthorn, and studded on each side with Narcissi and Primroses, planted first of all with a lavish hand by man and subsequently in riotous profusion by Nature. This second glen, which leads the visitor back towards the mansion, is in many ways a replica of the first, except that more water is present, thus enabling some very fine grouping of Japanese Irises to be carried out. Bamboos, Palms and Tree Ferns abound on every hand, and the accompanying illustration, from a photograph taken in this glen, will give our readers some slight idea of the dimensions that the Tree Ferns attain.

Leaving this second glen and travelling towards the mansion, the visitor passes along an avenue of Palms to the Lapageria walk, where these plants, both white and red flowered forms, fling their slender shoots in great profusion over trellis and pergola, constructed of home-grown Bamboos, while, near by, Clematis indivisa, with its myriads of dainty white flowers, may be seen scrambling over the branches of tall trees situated near by. On a wall that extends from the Lapageria walk we were pleased to notice *Abutilon megapotamicum* in flower, and Mr. Chapell, the head-gardener, informed us that it had bloomed all the winter, as had a magnificent specimen of *Gianthus Dampieri*, the first bloom of which opened on November 26.

In still closer proximity to the house is a spacious, sloping lawn, in the beds of which a wonderful collection of rare trees and shrubs finds a home. A few of the more interesting of these at the time of our visit were *Drimys Winteri*, a beautiful seedling *Acacia*, *Plagianthus velutinus* (which had made a fine tree and flowered freely the previous year), *Clethra arborea*, a magnificent plant of *Rhododendron ferrugineum*, the Loquat (*Eriobotrya japonica*), a fine tree of *Embothrium coccineum*, *Pittosporum speciosum* (with dark green foliage that has beautiful silvery tomentum on the under surface and flowers of deep blood red), *Brachyglottis repanda*, a fine plant of *Feijoa sellowiana*, *Magnolia Campbellii* (which blooms here), *Eucalyptus globulus* (over 70 feet high) and *Drimys aromatica*. *Rhododendron Nuttallii* blossoms in the open here. By the margins of a natural-looking pool situated in this lawn Royal Ferns, Gunneras and numerous other moisture-loving plants flourish in abundance, imparting to the whole an air of tranquillity that is too often missing in otherwise excellent gardens.

A great deal more might be said about the treasures to be found in the gardens and glens at Bosahan, but enough has been mentioned to indicate what a vast amount of enjoyment awaits the plant-lover who is fortunate enough to visit this most delectable spot in a far-off and too-

little-known corner of England. Before closing, we would express our thanks to Sir Arthur Vivian for allowing us to see his many treasures and to place particulars of a few, at least, of them before our readers. Our thanks are also due to the steward, Mr. Cranford, who went to Bosahan when Sir Arthur built the house; and to the head-gardener, Mr. Chapell, for their courtesy so freely extended to us.

THE ORIENTAL POPPIES.

THE large-flowered herbaceous plants known under the general name of Oriental Poppies form one of the brightest and most interesting features of our borders and large lawn beds during the month of June, the floral display sometimes being prolonged well into July. The old scarlet flower, with its boss of black anthers, has for many

CROCUS SUSIANUS.

ALTHOUGH not a flower that everyone would care to grow, this charming little *Crocus* is a great favourite with many. It is frequently referred to as Cloth of Gold, but it is necessary to see its flowers fully opened to recognise it by this name. To the writer the blossoms of this *Crocus* are most pleasing before they open wide, *i.e.*, just as they push up from the rather inconspicuous tuft of delicate green leaves. When in this condition the beautiful markings on the outsides of the floral segments are seen to the best advantage. These take the form of perpendicular blotches of deep glossy bronze maroon, one to each segment, and between these blotches the orange yellow basal colour shows itself in a most attractive manner. This little *Crocus* is a native of the

TREE FERNS GROWING IN THE OPEN IN THE GARDENS AT BOSAHAN, CORNWALL

years been a familiar plant to us all; but during the last decade a number of other varieties, differing chiefly in the colour of their blossoms, have been raised and put into commerce. Unfortunately, some of these are not good garden plants, inasmuch as their flowers lack that clearness of colour that is essential in plants suitable for adding beauty to the outdoor garden. One of the best of the new-comers is Jeannie Mawson. This has large, bold flowers of rich salmon pink tint, with purple blotches at the bases of the petals. Cerise Beauty, as its name implies, is coloured cerise pink, and is a most attractive flower when well grown. In Princess Ena we have a light orange salmon Poppy of great charm, and one that is delightful as a cut flower. In common with other members of the family, the Oriental Poppies should be cut just when the buds are bursting. They will then open freely in water and reveal to the fullest extent the delicate beauty of the crimped petals.

Crimea, and although it has been known in this country for a long time, it does not appear to have made any great headway in popular favour. It opens its blossoms during the early part of February, and this year one plant in my garden was flowering before January had departed. It is one of the best *Crocuses* for planting in grass, but, like all of its kin, it should be given a sunny position. Grown in shallow pans or pots in a cold frame or a quite cool greenhouse, it is a charming little plant for indoor decoration, where its rather delicate beauty can be developed to the full without fear of injury by birds or ungenial weather. In common with most, if not all, other *Crocuses*, it will not stand hard forcing; it should be allowed to develop under as natural and cool conditions as possible. Corn can be purchased very cheaply, and it is not yet too late to plant, though the earlier they are put in the better.

ROSE-GROWING IN TOWN GARDENS.

GOOD red Roses are always welcome, and most town gardeners are glad of an opportunity to add to their collections. Really fine novelties of this colouring are certainly scarce among the Hybrid Teas, and we must still look to the future for perfection. Of recent introductions the majority have been bedding Roses, and, of these, one of the best is Mrs. Edward Powell. In colour it is described as scarlet, shaded with purplish crimson, but this description hardly does it justice, for the crimson predominates and the shade is entirely pleasing, which means that the purple is scarcely perceptible. Growth and habit are both excellent, but perhaps the finest feature of this Rose is its beautiful foliage, of a rich reddish brown in the new growth, changing to a deep bronzy green as it hardens. It is affected hardly at all by mildew, and, being very free flowering, the variety is one that may be confidently recommended for towns.

From the Rose-grower's point of view, the present season has been chiefly remarkable for its several prolonged periods of dryness. One effect of this has been to bring out in many kinds the good points which are only suspected in a more humid season. Roses such as the Cochetts and Mme. Constant Soupert, which are naturally bad openers, have given no trouble at all, while even Souvenir de Pierre Notting, worst of all good Roses in this respect, has expanded quite freely almost throughout the season. If dry weather benefits some Roses, there are many that it affects adversely. Kinds which are described as good in a cool season, it may safely be assumed, will not show to great advantage when conditions are the reverse. Captain Hayward, Frau Karl Druschki and Lady Ashtown, to mention only three, are among those likely to suffer, while the kinds with but few rows of petals, such as Mme. Melanie Soupert and Betty, are so soon over that their full beauty can hardly be seen.

A propos of thin Roses, there are now many beautiful singles which are rightly appreciated both for their effect in the garden and for decoration indoors. Of the "Irish" family, one cannot but think that Irish Elegance still retains first place. Irish Fireflame does not appear to find the English climate as favourable as that of its native land. As to whether these kinds are suitable for town gardens is a question which depends greatly upon the space at one's disposal. To be seen at its best, Irish Elegance needs to be massed in a bed of fair size. It is a large grower, and this, as well as the delicacy of its colouring, make it difficult to group with other Roses; but

those who can spare the room should certainly have a bed of it, even if it consists of only half a dozen plants.

Red-Letter Day, another of Messrs. Alex. Dickson and Sons' productions, is one of the most beautiful and conspicuous semi-double Roses, and shows to great advantage even in a small group of plants, the colour being a particularly warm shade of scarlet crimson. P. L. GODDARD.

ROSE NERISSA.

THIS charming Hybrid Tea Rose was raised by Messrs. William Paul and Sons of Waltham Cross, and when first shown by them in 1911 was promptly noted as a superb addition to Roses of creamy

ROSE NERISSA, A BEAUTIFUL CREAMY YELLOW HYBRID TEA.

yellow tint. Since then I have been able to test it and in that way prove its capabilities, especially as a garden variety. It has a vigorous habit, and the exquisitely shaped flowers are borne on long, stout stems; hence it is particularly valuable for cutting. The exhibitor will find it a most useful variety, as the blooms, in addition to their perfect shape, always possess plenty of fulness and substance. When shown before the Royal Horticultural Society on July 18, 1911, this Rose received an award of merit, a distinction that was undoubtedly well deserved. The accompanying illustration gives a good idea of the superb shape and fulness of the flowers, though it cannot convey the refinement that is so characteristic of this variety.

SEASONABLE NOTES ON VEGETABLES.

Asparagus.—As the tops are now thoroughly ripened, they should be cut off within 2 inches of the soil. Clear the beds of weeds, lightly fork or hoe over the surface, and cover the beds to a depth of 2 inches with half-decayed farmyard manure. If the beds are to be made extra tidy, cover the manure with a thin layer of soil from the alleys between the beds, chopping down the sides neatly. If strong crowns are available, the roots may be lifted and forced for an early supply. A hot-bed in a pit or cold frame is a suitable site. Collect the necessary material—long, strawy manure from the stable, Oak and Beech leaves—and throw it into a heap to induce it to ferment, when the bed can be made on which the frame is to stand. Note the temperature in the frame, and when it declines to about 65° the soil and roots should be put in. Three inches of compost—old potting soil, leaf-mould and finely sifted horse-manure—will suffice. A thickness of 3 inches under the roots and 2 inches over them when placed in position as near together as possible, without being overcrowded, will answer well. Keep the frame close until growth commences; then give a little air. Syringe the soil twice daily with tepid water. Maintain a temperature in the frame of 60° by the aid of outside linings of fresh manure and covering the glass with mats.

Lettuce.—Continue to prick out small plants in frames for future use, covering the soil with coal-ashes to prevent slugs devouring the plants. When these are established, give abundance of air to induce sturdy growth, removing the lights entirely when the weather is favourable. When there is a danger of the supply outside running short, remove a batch of plants to a frame, as there they will grow more quickly.

Celery.—The last earthing of the latest crop should be completed without delay, sloping the soil on each side of the rows sharply to prevent heavy rains getting down to the hearts of the

plants in quantity, as in the case of heavy soil an excess of moisture is harmful. A supply of litter, straw or Bracken should be at hand for covering the rows in case of severe frost setting in.

Tomatoes.—Young plants intended for fruiting during February or March next year should be kept near the glass in a buoyant atmosphere and a temperature of not less than 60°. Those plants with fruit now ripening should have a light position near the glass in a temperature of not less than 65°, with a rather dry atmosphere.

Autumn-Sown Onions are looking remarkably well. The seed germinated satisfactorily, and now there is an abundant supply of green Onions suitable for salads, in addition to the quantity required for the usual crop. Keep the plants

tree from weeds, so that the growth from now onwards will be of a stocky character.

Cauliflowers of the Autumn Giant or Self-Protecting type not sufficiently advanced for cutting should be lifted and heeled in in cold frames or at the foot of a south wall, where they can easily be protected in the case of sharp frost. Plants intended for putting out early next year should be potted singly in 3-inch pots and plunged in coal-ashes in a cold frame, drawing off the lights as the weather permits to encourage sturdy growth.

Mushrooms.—Continue to prepare the manure for additional beds by frequent turning, so as to let off surplus steam and heat. Spawn earlier-made beds as soon as the temperature declines to 75°, using pieces of spawn 2 inches square every 9 inches

A ROSEMARY FOR THE ROCK GARDEN.

EVEN during its brightest periods the rock garden owes something to the dwarf-growing shrubs which are usually planted between the large boulders, and during the winter and late summer months such shrubs relieve to a great extent the bareness that is frequently associated with the rock garden at those seasons. A charming little shrub for this purpose, and one that does not seem to be at all well known, is the dwarf form of the common Rosemary known as *Rosmarinus prostrata*. This has the old-world fragrance that renders the taller-growing kind

or it might with advantage be planted by a doorstep where the tall-growing kind cannot be accommodated. Sweet-smelling shrubs are none too plentiful, and we ought to make the fullest use of those which are available.

THE SUNK GARDEN AT SUTTON PLACE.

No doubt the sixteenth century gardens of Sutton Place, Surrey, were furnished with a richness which matched the splendid architecture of the house, but few traces of them were visible when Lord Northcliffe made it his home. It fell to

THE NEW SUNK GARDEN AT SUTTON PLACE, SURREY.

apart, burying the spawn in the bed about two inches deep. Sprinkle over the surface of the bed a small quantity of prepared manure, finally ramming the whole down firmly with a brick. Soiling should not be done for a few days after spawning. The soil being in a moist state, it is easily smoothed over and made firm with the back of a spade. Finally cover the bed with litter to prevent the soil drying too rapidly.

Cardoons.—The latest batch of plants should be prepared for blanching, as growth is now almost completed. Wrap around each stem a piece of brown paper 6 inches wide, covering this with a hay-band tightly woven around, and finally bank up with soil

See more.

E. MOLYNEUX

so delightful, and, indeed, only differs from it in habit and somewhat smaller foliage. Instead of forming the columnar bushes that we so often see in old-fashioned cottage gardens, the prostrate variety keeps close to Mother Earth, and at all seasons is a source of satisfaction to its owner. In late spring, when lavishly bedecked with its quaint lavender blue flowers, this little shrub is second to none. It should be given a rather warm position and porous soil, yet it ought not to be so placed that it will suffer from drought during the scorching days of summer. If these points are borne in mind, it is not more difficult to grow than the tall Rosemary, and need not be confined to the rock garden. For instance, as an edging to the herb garden it would be delightful

Lady Northcliffe to employ her charming taste in recreating a fitting garden frame for the Tudor building. To the west of the office quadrangle there remained the old walled gardens. An octagonal summer-house stood at their northern intersection. It is probably the oldest garden feature remaining at Sutton, and is seen in the accompanying picture, which also shows a modern shelter designed on the same lines. The enclosure has been laid out with delightful effect. A square panel has been sunk, and its dry retaining walls are gay with alpine. In the middle is a round pool, its margin planted with *Iris Kämpferi* and other water-loving things. Sheltered beneath the walls are broad herbaceous borders filled with tall-growing plant

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Fruit Trees in Pots which are still in the open should be placed in a bed of ashes and plunged to the rims of the pots as a protection from frost, and a further covering of leaves should afterwards be placed over the surface when sharp frost sets in. If American blight is present on the Apple trees, they may be carefully dressed with some approved preparation while the trees are dormant. Peach and Nectarine trees in pots which are intended for succession should now be placed under cover and the ventilators left open during mild weather.

Tomatoes.—A sowing ought to be made now to produce plants for spring fruiting. As soon as the young plants are well through the surface they should be placed quite close to the roof glass in a temperature of 60°. Pot into small, clean pots as soon as large enough. Endeavour to grow the plants as stocky and short-jointed as possible. Plants from which fruits are being gathered must be carefully watered throughout the winter months, and ventilation given when external conditions permit.

Plants Under Glass.

Plumbago rosea.—This charming winter-flowering plant succeeds best when allowed to remain through the flowering period in a warm conservatory or intermediate stove where the atmosphere is somewhat dry and where a little air can be admitted when the weather is favourable. If choice flowers are in demand, a very pleasing effect may be produced by associating *Plumbago rosea* with *Lily of the Valley*, *Roman Hyacinths* and good fronds of *Adiantum*.

Freesias.—As soon as the plants are a few inches high, they should be removed from the cold pit to a warm greenhouse and placed near the glass. At this stage a few twigs ought to be placed in position to afford the necessary support. When the pots are well filled with roots, weak manure-water may be applied with advantage.

Sweet Violets.—Now that the plants have become well rooted in the new soil, it is hardly possible to give too much air, providing the weather is mild. At Frogmore the lights are removed every morning and only partly closed at night until sharp frost sets in. Remove all decaying foliage and see that the roots are well supplied with clear soft water.

The Flower Garden.

Lifting Chrysanthemums.—Now that the flowering season is over, a sufficient number of healthy roots should be lifted and placed in a cold frame with a view to producing cuttings for next season's stock. By the end of January plenty of stocky cuttings will be available for propagation.

Herbaceous Borders which have recently been planted should be lightly pricked over as soon as possible, taking care not to disturb any of the newly planted subjects. A careful watch must be kept for slugs, which will soon work havoc if not destroyed. Borders where lifting and dividing are unnecessary should be carefully cut over and a dressing of decayed horse-manure or leaf-soil lightly forked in among the plants. Any strong-growing subjects which have grown beyond bounds may be lifted and replanted with a view to bringing them more in keeping with their surroundings.

The Hardy Fruit Garden.

Strawberries.—Autumn-planted Strawberry quarters will require a light forking over, but previous to this the weeds should be removed, and if the ground is dry enough, this ought to be carefully trodden round the plants. Plants in older beds which are intended to fruit another season must be carefully trimmed up and all weeds and decaying foliage removed. Fork the surface very lightly, and if necessary give a light dressing of decayed manure, to be washed into the soil during the winter.

Raspberries.—November is the best month to make new plantations of Raspberries. Let

the soil be trenched 2 feet deep and enriched with good farmyard manure. To obtain the best results it is necessary to make new plantations every five or six years, and, in selecting the suckers for these, those produced by old, worn-out plants should be avoided. It is better practice to obtain a fresh stock from the nursery than to plant suckers which have been grown on the same place too long. As regards the method of planting, the space between the rows ought to be at least 6 feet, and if double this distance so much the better, as low-growing vegetables may be planted between, and the crop will be much heavier and the fruits larger in consequence of a free circulation of light and air among the plants.

The Kitchen Garden.

Seakale Forcing.—As soon as the foliage has died down, a few roots may be taken up and placed in some dark chamber with sufficient heat to start them into growth. If only a small supply is necessary, the Mushroom-house is a good place to grow it. If large pots are available, the roots should be placed in good rich soil to within an inch of the crown, and this made firm with the fingers. Each pot ought to contain sufficient roots to supply a dish of Seakale, and the pot may be kept in perfect darkness by another of the same size being turned upside down and covered with clean leaves to exclude both light and air. A temperature of 60° will be quite high enough for the purpose. One good watering should be sufficient, providing the surroundings are kept moist.

French Beans in Pots should be freely supplied with manure-water. Keep the plants well exposed to the light, and provide sufficient sticks to keep the plants in an upright position. At night 60° will be a suitable temperature for them.

Mint and Tarragon.—As soon as the foliage has died down, a number of plants ought to be lifted and placed over a gentle hot-bed in order to produce green shoots for the daily supply. The hot-bed should be trodden tightly and a covering of sifted soil placed over the surface. The roots must then be put in position and covered with 2 inches of fine leaf-soil. Water should then be applied at a temperature of 70°.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Turnips.—Any late-sown Turnips still in the ground should now be lifted and stored in sand. Larger quantities will keep well enough in pits similar to those used for Potatoes. It should be remembered that they will keep much longer if the leaves are broken off and not cut, as is usually done. They had better be stored where they can be easily got at in rough weather.

Carrots in Frames.—Where the forcing of these is intended, preparations must now be made with that end in view. At the outset it should be pointed out that this is a vegetable that will not respond readily to undue forcing. If artificial heat is not available, the frames ought to be protected by hot-bed material, and as the roots will be used when quite small, the frames may be made up almost entirely of sand. From this date a small sowing should be made every three weeks, which in most cases meets the demand.

Broad Beans.—In view of the fact that this crop takes a long time to come to maturity, it is doubtful if the seeds in the majority of cases are sown early enough. I have always advocated the sowing of this crop in the autumn, even among farmers, and, provided a certain amount of growth is made before the end of the year, there is very little danger of the crop being affected by frost. Sowings made now should be on a warm border, if possible sheltered from the north, and if planted close enough, it is surprising what a useful crop may be secured quite early in the season.

The Flower Garden.

Moss on Lawns.—Should the weather be favourable, opportunity ought to be taken to get rid of moss patches on the lawn, which at this season of the year are very conspicuous. For this work a good sharp-toothed rake should be used,

going over the lawn several times. Afterwards have the moss swept off. In most cases the presence of moss is a sure sign of poverty, so that in top-dressing it will be advisable to mix some approved lawn manure with the compost. The compost must be spread evenly over the surface and allowed to remain thus until the spring, when a further dressing may be given; then have the lawn rolled.

Border Carnations.—Now that severe weather may be expected, extra care should be taken to see that these Carnations are safely guarded against rabbits and other pests. Where it is not possible to use wire-netting, I may repeat the advice I gave in the spring; that is, to stretch pieces of string round them about six inches from the ground, and paint the string with Renardine about every three weeks. The possibilities are that no further trouble need be feared. This preparation can be had from Messrs. Gilbertson and Page, Limited, Hertford.

Herbaceous Plants.—As already pointed out, the work of replanting some of the earlier-flowering subjects should not be delayed, provided, of course, the weather will permit of planting being done. While quite a large number of herbaceous plants may be moved about freely, there are others which suffer more or less from disturbance. These include Anemones, Tritomas, Lathyrus and many others of a similar nature, and, provided the soil is fairly good, they need not be disturbed more than once in four or five years.

Plants Under Glass.

Forcing Plants.—Quite a number of flowering plants may now be introduced into a heated pit and brought on gradually. These will include Azaleas, *Deutzia gracilis* and *Spiræas*, which are indispensable even in the most modest collection. Except in the case of *Spiræas*, very little water will be required at this stage; a slight syringing will suffice for a time. *Lily of the Valley* clumps lifted from the open border may be placed in boxes, which will supply useful flowers for cutting. These last somewhat longer in a cut state than those from retarded crowns. *Roman Hyacinths* should be brought on in small batches to keep up a continuous supply.

Chrysanthemums.—As the single-stemmed varieties are cut over, the plants ought to be stood where they will be secure from frost. Place them where they will be exposed to the light, so that good, healthy cuttings will result. Very often the plants are allowed to lie about in odd corners, with the result that cuttings are worse than useless. Plants that are shy in producing young growths should be placed in a little heat and carefully watered.

Cypripediums.—A number of the varieties will now be showing flowers, and although many of them are very erect in habit, others, again, will be seen to better advantage if they are staked up. Owing to the nature of the potting material, this work must be very carefully performed, otherwise much injury will be done to the tender roots. Very light stakes or Bamboo tips dipped in green paint should be used, and these ought to be so arranged as not to detract from the beauty of the flowers.

Liliums.—Many of the bulbs will soon be coming to hand, and it is important that these should be potted up almost immediately they are received. For ordinary purposes three bulbs in a 7-inch pot will be sufficient, and, in potting, place the bulbs so that ample room is left for top-dressing. These pots ought to be stood in frames and the plants brought on as required.

Fruit Under Glass.

Pot Vines.—Those intended to produce ripe Grapes early in May must now be placed in the forcing-house. The pots should be plunged in hot-bed material made up of Oak leaves and short litter. On no account must this bottom-heat be allowed to become excessive at any time, and, until the Vines start into growth, the temperature should not exceed 50°. The atmosphere ought to be kept fairly moist and the roots syringed with tepid water on all favourable occasions until growth commences. Water must be given with care, as it will be some weeks before root action is very active.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

CULTIVATION AND COLLECTION OF MEDICINAL PLANTS IN ENGLAND.

[The following has been recently published as Leaflet No. 288 by the Board of Agriculture.]

(Continued from page 558.)

DANDELION (*TARAXACUM OFFICINALE*, L.).

DANDELION has been scarce throughout 1914. English roots have usually been sold in competition with German roots at about 40s. per cwt., but 110s. was being paid in September. In the early part of this year fresh root was worth 6s. per cwt. Unless this year's collection is much greater than usual, the absence of German competition will keep prices high. Farmers might collect and dry the roots, or arrange with a middleman for this to be done for them. An advantage of this course is that the weed is reduced.

Cultivation.—About 4lb. of seeds per acre are drilled in rows a foot apart. Hoeing is needed to keep the crop clean. Flower-heads are picked off as they appear, before the winged seeds can be dispersed, otherwise the grower's own land and that of his neighbours will be smothered with the weed. The roots are dug the second year in autumn. They may be transported fresh for pressing out the juice or making dandelion extract, or be washed, sliced and dried. The yield should be 4 tons or 5 tons of fresh roots to the acre in the second year. A hundred parts of fresh root yield twenty-two parts of dry material.

FOXGLOVE (*DIGITALIS PURPUREA*, L.).

The Continental supplies of *Digitalis* leaves from Thuringia and the Harz Mountains are stopped, but there should be enough of the wild plant in England to satisfy home requirements if it can be collected. Dry wild leaves would be worth 35s. per cwt. and upwards. Unless these are gathered in considerable quantity, there will be a shortage next year.

The Foxglove is cultivated by a few growers in this country for a very limited market, in order to provide a drug of more uniform activity from a true type of *Digitalis purpurea*. *Digitalis* is cultivated in the partial shade of orchards, but it likes a moderate amount of sun. Its cultivation as a paying proposition to a fruit-grower can hardly be recommended. Its culture is that of a garden plant. *Digitalis* grows best in a well-drained, loose soil rich in leaf-mould. It is said to dislike chalk, but appears to grow well enough at Croydon and Darenth on calcareous soils. About 2lb. of seed are required per acre, and as the seeds are so small and light, they should be mixed with fine sand in order to ensure even distribution. They should be thinly covered with soil. The seeds are uncertain in germination.

The leaves are hand picked in the second year from flowering plants, the yield being about 1 ton to 2 tons of fresh leaves per acre. Great care is necessary in collecting and drying quickly, and a reputation for care is necessary if the crop is to be sold at remunerative prices.

DILL (*PEUCEDANUM GRAVEOLENS*, B. AND H.).

English Dill has long had a reputation of its own for distillation of essential oil. It is grown chiefly in East Anglia. Considerable shortage is already evident, following the stoppage of Continental supplies, the cheap Indian fruit not being an effective substitute. This annual is easily grown, and should pay well in years to come.

Cultivation is similar to that of spring Oats, 10lb. of seed being drilled to the acre. Careful attention must be given to the destruction of weeds. The plants require much watching as the time for harvesting approaches. Mowing is begun as the lower "seeds" (fruits) begin to fall, the others ripening on the straw. In dry periods cutting is best done in early morning or late evening. The loose sheaves are built into small stacks of about twenty sheaves tied together. In hot weather threshing may be done in the field. The crop is considered rather exhaustive of soil fertility. The yield is 5cwt. to 7cwt. of Dill fruits per acre, selling in normal periods at 30s. to 40s. per cwt.

(To be continued.)

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

TROUBLESOME WEED IN LAWN (*E. T. W.*).—The weed sent for name is the Self-heal, *Prunella vulgaris*. It is most common in badly drained ground, but is a common weed in many lawns. The best way to destroy it is to rake out as much of it as possible; then give the lawn a generous surface-dressing of farmyard manure, basic slag or bone-meal. Either of these will encourage the grass, and by its extra vigour it will then displace the weed.

ADVICE ON YUCCAS (*E. F. Brown*).—We advise you to plant the Yuccas in a sheltered, well-drained part of the garden. It is not necessary to put them under cover in the winter. As the leaves are quite healthy, they must be able to obtain a certain amount of nourishment, even though most of the woody matter has perished. In planting, the Yuccas should be put at such a depth that the decayed portion is below the surface of the soil. Then roots will in time be pushed out from the healthy part, and the plants again become established. Where the woody matter of the stems is decayed, it cannot be replaced; but when roots are produced from the healthy portion, the decay will not spread upward.

HERBACEOUS PLANTS AND BULBS (*M. B.*).—As the lawn appears to come right up to the hedge, it would be necessary to form a border of any width you please or to suit the circumstances of the case, and this, if properly trenched and manured, might be made to grow many things quite well. As the hedge is new, you have nothing to fear from the spread of roots, though it would be well in planting to keep at some distance, say 2 feet, from the stems of the plants. If you will give us the width and length of the border, we will endeavour to suggest something of service. You might say whether annuals or perennials would be preferred. Darwin Tulips should be planted 5 inches or 6 inches deep. Daffodils, if for purposes of naturalisation, would do quite well 4 inches deep, the larger-rooted sorts, as Emperor and others, being planted 6 inches deep. For small bulbs, as Snowdrop, Chionodoxa and Muscari, 4 inches deep would be ample, somewhat less if the soil is of a heavy nature. Rough ground will do quite well for many of these plants, though better results will be forthcoming if it is well trenched or even deeply dug prior to the planting.

DAFFODILS NOT DOING WELL (*D. F. R.*).—From your description of the bulbs it would appear they have fallen a prey to the fungus disease known as *Fusarium bulbigenum*, which during the past few years has been giving trouble to cultivators both in Holland and England. There is no cure, and at present no known preventive. All you can do is to burn the bulbs. You might also, with a view to limiting its spread, mark the places of any groups of bulbs bearing signs of leaf disease for early lifting and examination, and as a precautionary measure dust with sulphur, though as the fungus appears to permeate the inner tissues of the bulb, this is not likely to prove very effective. As to the soil whence the diseased bulbs came, we should certainly avoid it for Daffodils, and give it a good dressing of finely powdered lime in addition. In this way the soil should be of service in growing Montbretias and other bulbous-rooted plants. The only way to avoid "more rotting" or to limit its spread is by annual lifting, drying and cleaning. Lift the bulbs in July, and having dried them in an airy shed in shallow, open trays, keep them under observation and burn all affected bulbs at once.

PLANTS FOR BORDER (*Flora*).—You will find the following of service both for the border and for cutting. A 3-foot-wide border will not admit of more than two rows of plants, which should be arranged alternately to afford them as much room as possible. As the fence is low and no trees exist, it will be possible to keep the back line quite near the fence, the plants being set 2 feet apart. Those in the front row should be 18 inches apart. For the back row: *Aster ericoides* Desiro (white), *A. Novi-Belgii* densus (blue), *Anemone japonica* alba, *A. j. elegans*, *A. Amellus* Riverslea (violet), *Phlox* Mrs. E. H. Jenkins

(white), *P. Flambeau* (scarlet), *P. Le Mahdi* (violet), *Pyrethrum Hamlet* (pink), *P. James Kelway* (crimson), *P. Ne Plus Ultra* (blush), *Lilium candidum* (white—three or six bulbs should be set in a group), *Delphinium Belladonna* (clear blue), *D. King of Delphiniums* (dark blue), *Iris* Mrs. C. Darwin, *I. Mme. Chereau*, *I. pallida* and *Gaillardia grandiflora*. For the front row: *Aster levigatus* (rose), *Helenium pumilum* (yellow), *Lilium pyrenaicum* (yellow), *L. umbellatum* (orange), *Pentstemon Newbury* Gem (scarlet), *Coreopsis lanceolata* (golden), *Campanula glomerata dahurica* (dark blue), *Achillea alpina* (white), *Aster subcaruleus* (blue), *Heuchera sanguinea* (scarlet), *H. brizoides* (rosy), *Hemerocallis Dumortieri* (orange), *Geum Heldreichii* (orange yellow), *Geranium Endressii* (rose), *Gentiana acaulis* (deep blue), *Dicentra eximia* (rosy), *Campanula carpatica* (blue), *C. c. alba* (white), *C. c. Riverslea* (dark blue), *C. muralis* (blue), *C. G. F. Wilson*, *Aubrietia* Dr. Mules (violet), *A. Fire King* and *Anemone sylvestris* (white).

PLANTING HERBACEOUS BORDERS (*S. D. P.*).—If the failure to which you refer concerns the past season more particularly, we should consider it to be due to the long-continued drought, or it might be this in conjunction with undue preparation of the borders. All hot, sandy soils require specially deep working and enriching with manure, and with cow-manure, by reason of its cooling nature, for preference. With some knowledge of the soil of your district, we know also the difficulty of inducing the usual run of vigorous-growing herbaceous plants to thrive, and we know, too, that in many instances this year such plants have been more or less burnt up. With due preparation of the soil in such a case, annual replanting in the autumn should also be indulged in, so that the plants may obtain a good hold of the soil. In addition, a good lime dressing during the process of soil preparation would be helpful. A greater success, too, may be ensured in those instances where the borders are quite removed from tree life, and when the surface soil is either kept flat or is below that of the surrounding soil. This would admit of an occasional flooding of water in times of great drought, when, with the assistance of some artificial manure, a fuller measure of success might be achieved. As you say the annuals have not done well—these have given excellent displays in most dry, gravelly soils this year—we can only conclude that soil poverty as much as drought has been at the root of the trouble. In all probability a little expert advice on the spot would be money well spent. Some of the more showy plants calculated to succeed with the treatment we have in mind would be the Italian Starworts in variety, *Campanula carpatica* in several varieties, also *Hendersonii* and *Hillside* Gem, *Stokesia*, *Anemone japonica* in variety, *Cimicifuga simplex*, a set of florists' *Pentstemons* to be planted in March or April, *Rudbeckia*, a selection of *Phloxes*, *Carnations* and *Michaelmas Daisies* in variety should also provide what you require. Among annuals, *Godetia*, *Rocket*, *Larkspur*, *Lavatera*, *Alonsoa*, *Nigella*, *Snapdragons* and *Stocks*. So far as selection goes, we can only generalise, as you do not give the size of the borders. The partial failure of the Lupines is due probably to the same cause.

TREES AND SHRUBS.

PLANTS FOR SCREEN (*M. L. W.*).—You cannot do better than plant common Holly in the position you describe. Plants 5 feet to 7 feet high can be procured, but they had better not be obtained before the end of April, as they do not transplant well during late autumn and winter.

TO KILL TREE STUMP (*E. F. Brown*).—The stump of a tree can be killed by exposing the principal roots and boring holes well into the middle of each root, afterwards filling the holes with salt. A more rapid method is to water the ground round about with weed-killer, but it poisons the soil and makes it unfit for other vegetation for a considerable time. You can obtain information about stocks for fruit trees in "Fruit Growing for Beginners," by F. W. Harvey, published by *Country Life*, Limited, 20, Tavistock Street, Covent Garden, W.C., price 1s., or post free 1s. 3d. A shilling book on "Trees and Shrubs," including methods of propagation, is published by Messrs. Cassell and Co., and is entitled "Pictorial Practical Tree and Shrub Culture." A more comprehensive book upon the same subject, entitled "Trees and Shrubs," by E. T. Cook, price 12s. 6d., is published by *Country Life*, Limited, as above.

ROSE GARDEN.

ROSES FOR NEW BED (*Chatenay*).—You should be able to make an effective bed of Roses in the plot of land described, providing you have the soil dug at least 2½ feet deep and plenty of good manure incorporated with the lower soil. We advise keeping the Roses at least 5 feet away from the Laurel hedge. The Roses can be planted as close as 18 inches apart, in order to have a good effect of colour. As you name Mme. Abel Chatenay, we suggest planting this at the end furthest from the windows, as it is a tall grower; then, to follow it, *Caroline Testout*, *Lady Ashtown* or *Betty*, with the *Monthly Rose* Mme. E. Resal in front. An alternative scheme would be *General Macarthur* (scarlet) at the back, Mme. Abel Chatenay next, with Mme. Ravary (golden) in front; or Mme. Abel Chatenay, Mme. Ravary, and the scarlet *Polyantha* Rose *Jessie* in front. All these are very free, continuous and inexpensive. Any of our Rose advertisers would supply these. The plants may be heeled in in the kitchen garden soil for several weeks until such time as you can plant them. If you could give us the exact width and length, we would advise you how many plants to procure.

MISCELLANEOUS.

USE OF SULPHATE OF POTASH (D. G.).—Sulphate of potash is not injurious to any plants as long as you do not use more than half an ounce to 2oz. to the square yard, but is, on the contrary, likely to be very beneficial on many soils.

NAMES OF PLANTS.—*Herbert Lester.*—The Dahlias sent were very poor and naturally out of colour in November. 2, Britannia; 4, Mrs. H. L. Brousson; 6, Phoebe; 94, too poor to recognise; 135, Mary Service.

NAMES OF FRUIT.—*R. Pope.*—1, Cellini Pippin; 2, Norfolk Beauffin. —*J. Wright.*—Beurée Hardy. —*Ribble.*—Durondeau. —*Lielie.*—1, Beurée Dumont; 2, Vicar of Winkfield; 3, Eister Beurée; 4, Northern Greening; 5, Blenheim Orange; 6, Kedleston Pippin; 7, Aston Town; 8, Durondeau. —*D. C. Lysaght.*—1, Very fine fruit of Blenheim Orange; 2, Lord Derby. The Pear was too decayed to identify.

SOCIETIES.

LIVERPOOL HORTICULTURAL ASSOCIATION.

THE executive of the above society, owing to the war, made their show into a non-competitive exhibition, with an open request that all fruits, plants and flowers might be sold and the proceeds given to the Relief Fund. The outcome was a generous one, the large Corn Exchange being well furnished on the 11th inst. with a varied assortment from well-kept gardens. Something novel was expected under the new regulation, where the exhibitor could adopt whatever system he desired and stage his exhibit at his own sweet will. The change was not very great. In some exhibits skill and taste created gratifying results, but in many cases overcrowding spoilt the effect. Although the show was non-competitive, honorary awards were made to the more important features in the form of gold and silver medals and certificates of merit. We can only notice briefly a few of the exhibits out of the seventy entries and those who were favourably accepted by the judges.

Gold medals were awarded to the following exhibitors: Mr. G. Haigh, gardener to Sir W. H. Tate, Bart., Woolton, who made a brave show of fine Chrysanthemum blooms on a groundwork of Palms, Ferns, &c.; Mr. P. Counce, gardener to G. Nicholson, Esq., Prince's Park, Liverpool, who staged eleven vases of splendid single Chrysanthemums with about a dozen blooms in each vase—a highly meritorious exhibit; Mr. P. Jakeman, gardener to Sir W. B. Forwood, Bart., Bromborough Hall, who contributed five dozen Japanese blooms of splendid exhibition form; Messrs. Dickson and Robinson, Manchester, who set up an imposing bank of decorative varieties, showing great taste in arrangement; Mr. W. J. Lockett, Grassendale, who had a pleasing collection of Chrysanthemums and fruit; Frank Bibby, Esq., Shrewsbury, who had a similar stand with noteworthy fruit; Messrs. Stuart Low and Co., Bush Hill Park, Enfield, who had a pleasing combination of Roses and Carnations set up in pillar form on velvet—the Roses were charming for the season; Mr. J. Lee, Bebbington, who fully maintained his high prestige as a successful fruit-grower; and Messrs. R. P. Ker and Son, Aigburth, who added to the general effect with their fine stately Palms in considerable numbers.

Silver medals.—A large number staged the popular autumn flower, and excellent selections were set up by Mr. J. Stoney, gardener to Lieutenant-Colonel J. B. Gaskell, Woolton; Mr. J. George, gardener to T. Henshaw, Esq., Roby; Mr. H. Middlehurst, Liverpool; and Mr. Loo Thompson, Formby. Messrs. John Cowan and Co., Gateacre, were the sole representatives of Orchids. Fruit had numerous supporters. Mr. E. Bennett, gardener to J. E. Gordon, Esq., Chester; Mr. J. Gibbins, gardener to the Countess of Sefton, Croxteth; and Mr. Ben Ashton, gardener to the Earl of Lathom, were specially noteworthy with excellent collections. Mr. R. Manson, Gateacre, had bowls of bulbs, Palms, &c.; and Mr. C. A. Young, West Derby, Carnations staged on velvet.

Decorative tables were well shown by Messrs. Fishlock Brothers, Liverpool; Miss G. Milne, Waterloo; Miss Pollard, Liverpool; Miss Newsome, Ormskirk; and Mrs. Stephenson, assisted from her Liverpool roof garden.

Auction sales were held during the afternoon and evening, and these, with a small army of retail sellers, realised £110, which the executive hope to make a good addition to by the fruit unsold. Unfortunately, the weather was very bad, torrential rain falling nearly the whole of the day.

DULWICH CHRYSANTHEMUM SOCIETY.

THE twenty-first exhibition of this excellently managed society was a fitting celebration of its coming-of-age. Mr. R. B. Leech, the esteemed hon. secretary, takes a great interest in the work of this society, and is largely responsible for the introduction of several novel and pleasing features, which combine to make the show a great success. The exhibition is usually held at the Baths, Goose Green, but as the building had been commandeered for the Belgian refugees, St. Barnabas' Parish Hall, Dulwich Village, was utilised instead.

In front of the platform Mr. Leech, gardener to J. C. Eno, Esq., Wood Hall, Dulwich, S.E., set up a large, attractive group of Chrysanthemums and fine foliaged plants, which was much admired.

One of the chief competitive classes was a table group 8 feet by 4 feet, to comprise Chrysanthemums arranged

in vases, &c., and cut foliage and foliage plants, equal points being given for quality and effect. The judges placed Mr. A. Winter, The Gardens, Elm Lodge, College Road, Dulwich, S.E., first with a rather formal arrangement of very heavy blooms and beautiful foliage and foliage plants. A more artistic arrangement was set up by Mr. Leech, who had smaller blooms, but in several types the Chrysanthemum was charmingly displayed, with good foliage and foliage plants. This exhibit was placed second.

Another interesting class was for four varieties of Japanese, to be shown in vases, three blooms of one variety in each vase. A superb series placed Mr. J. Vanstone first, the varieties being Queen Mary, Lady Talbot, Mrs. Gilbert Drabble and F. S. Vallis. Mr. A. Winter was second, and Mr. T. Martin third.

Very handsome indeed were the four individual vases of decorative Chrysanthemums arranged for effect. A well-arranged vase placed Mr. L. Wheeler, The Gardens, Wood Hall, Dulwich, S.E., first. Another handsome vase from Mr. W. P. Barnes was placed second, and a good exhibit found Mr. T. W. Cliff third.

A competition that pleased us very much was that for two stands or vases of large blooms arranged with foliage for effect and with not more than eighteen large blooms in each stand, &c. This served to illustrate how monster blooms could be used in decorations. Two superb stands won first prize for Mr. R. B. Leech, who disposed his flowers and foliage most artistically. Second prize was awarded to Mr. Winter, who showed well, but less praiseworthy than that of the first prize exhibit. Bamboo stands were used.

One other class is worthy of notice. This was eleven Japanese blooms, distinct, to be shown on boards provided by the society. The boards were exceptionally large, and allowed 10 inches for each bloom, four blooms back and front, and three blooms in the middle row. Handsome blooms secured first prize for Mr. Winter, Queen Mary, Lady Talbot, Kara Dow, Bessie Godfrey and T. Lunt being his best blooms.

There were numerous other classes, all quite good, and we should think this society's exhibition is one of the most go-ahead of its kind.

The group of singles, as well as the group of large Japanese and other exhibition and decorative Chrysanthemums as shown by Mr. Norman Davis, were quite a feature of this splendid show. The singles were exceptionally good, and included such sorts as Juno (very large indeed), Isobel Felton, Mrs. W. Smith (white), Mensa, Joey Saunders, James Beats (bronze), Miss Molly Godfrey, Mary Morris and Thomas Ward.

Messrs. J. Peed and Son, West Norwood, also had a display of Chrysanthemums.

No prizes were awarded, and the whole of the proceeds, including the sales of flowers, &c., were to be given to the Prince of Wales' Fund. The society seemed sanguine of being able to raise about £60—a most commendable enterprise.

EDINBURGH CHRYSANTHEMUM SHOW.

THE annual Chrysanthemum show of the Scottish Horticultural Association was held in the Waverley Market, Edinburgh, on November 12, 13 and 14. It was originally fixed for a week later, and it was generally anticipated that the show would be cancelled on account of the war. The Council, however, decided to proceed with the show and to devote the profits to the Red Cross and Belgian Relief Funds. As was expected, the competition was more limited than usual, and the large hall not so well filled as in former years; but the display, as a whole, was a capital one, and the quality generally of a high class. Some of the ordinary exhibitors were noteworthy for their absence through various causes, but others who entered the lists exhibited in an admirable way.

In the competitive classes for Chrysanthemum blooms, the leading class was that for the City of Edinburgh Queen Victoria Memorial Prizes, the first being the City of Edinburgh Memorial Cup and £12 for a display of double and single Chrysanthemums on a table 12 feet by 8 feet. This worthily fell to Mr. James Beats, Binrock, Dundee, a well-known competitor elsewhere, but new to this show, who did credit to himself by his table, which contained splendid blooms admirably staged. Mr. D. McLean, Raith, Kirkcaldy, made a good second; Mr. G. Scott, Seathwood, Dundee, came third; and Mr. D. Kidd, Carberry Tower, fourth.

The Scottish Challenge Cup for ten vases of Japanese Chrysanthemums went to Mr. James Small, Norwood, Alloa; second, Mr. G. Stewart, Tulliehallan; third, Mr. H. M'Skimming, Auchinault, Helensburgh. Other prize-takers with cut flowers were Mr. J. Waldie, Mr. G. Stewart, Mr. J. Small, Mr. F. Templeton, Mr. G. Anderson, Mr. R. Whannell, Mr. A. W. Elliot and Mr. J. M'Fadyen. Messrs. Young and Co.'s challenge cup for a vase of Perpetual-flowering Carnations was won by Mr. W. Game, Dupplin Castle. The open class for six vases of Chrysanthemums had as the winners Messrs. Todd and Co.

Bouquets and floral designs were capitally shown, Mr. James Beats carrying off the leading prizes in the open classes. Mr. D. Kidd, Carberry Tower, was first for the decorated dinner-table; second, Mr. Beats; third, Mr. G. Scott, Seathwood. Chrysanthemum plants were good, Mr. M. G. Michie winning most of the first prizes. In the general plant classes there was, as a rule, a good competition, and the prizes were well distributed, Mr. J. Templeton, Mr. A. Cameron, Mr. A. A. Law, Mr. G. Scott, Mr. W. Brew, Mr. G. Anderson, Mr. J. J. Staward, Mr. F. M. Urquhart, Mr. W. G. Pirie and Mr. A. Williams being among the leading exhibitors.

Fruit was, as usual at this show, of high quality. Mr. D. Kidd was awarded the first prize for his collection of

eight dishes. The class for four bunches of Grapes, distinct, proved a win for Mr. J. Middleton, Callender House, Falkirk; and other first prizes for Grapes went to Mr. W. Hunter, Mr. A. Gauld, Mr. W. Scott, Mr. J. M'Fadyen, Mr. Middleton, and Mr. Kidd. The Malcolm Dunn Memorial Prize, for twelve dishes of Apples grown in Scotland, was won by Mr. James Duff, Threave, Castle Douglas, the same exhibitor being first for eighteen dishes of Apples. For six varieties of Pears grown in Scotland, Mr. R. G. Sinclair, Congalton, led. Mr. R. Currie, Foxley Hall, Hereford, was first in the open class for Pears.

Vegetables were a capital section, and many good exhibits were shown. Mr. W. P. Bell, Bothwell Castle, secured the first prize for the collection; second, Mr. W. Harper, Tulliebelton.

The trade exhibits, although few, were capital, and added considerably to the value and interest of the show. A gold medal was given to Messrs. W. Wells and Co., Merstham, for a notable exhibit of Chrysanthemums of various classes and Carnations, the varieties including a number of novelties. A gold medal was also awarded to Messrs. Storrie and Storrie, Carse of Gowrie Nurseries, for one of their extensive exhibits of fruit trees, fruit, flowers, &c. About a hundred and fifty varieties of Apples were shown on this table of about seventy feet long. Messrs. Dobbie and Co., Edinburgh, received a similar award for their magnificent collection of Potatoes, with good Chrysanthemums. Messrs. R. B. Laird, Dickson and Son, Edinburgh, were given a silver-gilt medal for a good display of conifers, &c. A silver medal was awarded to Messrs. John Forbes (Hawick), Limited, for an exhibit which included a number of Carnations, Begonias, &c. Messrs. Laing and Mather, Kelso, sent Potatoes and other vegetables, to which a bronze medal was given.

A splendid group of Orchids came from Mr. Hindle, Blacket Place, Edinburgh, whose gardener, Mr. W. Holden, grows them well, and a gold medal was awarded for this valuable non-competitive exhibit.

The show was opened by the Marchioness of Linlithgow.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE monthly meeting of this society was held at the Royal Horticultural Society's Hall on November 9, over which Mr. Charles H. Curtis presided. The sums of £28 17s. 9d., £13 0s. 4d. and £5 5s. 10d., respectively, were passed for payment to the nominees of three deceased members. The sick pay for the month on the ordinary side was £68 4s. 3d., on the State side £34 14s. 4d., and maternity claims amounted to £10 10s. The treasurer, in giving the financial statement, stated that the trustees had invested a further £400 on behalf of the society. The secretary reported that seventy-five members had joined His Majesty's Forces.

CHELMSFORD AND DISTRICT GARDENERS' ASSOCIATION.

THE fourth meeting of the winter session was held in the East Anglian Institute of Agriculture on Friday last. Mr. J. H. Hull occupied the chair, and about sixty members were present. Previous to the lecture the annual exhibition was held. There were ten classes, with a total of fifty-one entries. The competition was keen, and the exhibits reflected great credit on the exhibitors. In the fruit classes the judges had to award three extra prizes. Later in the evening the president, Mr. E. H. Christy, gave an interesting lecture on "Sweet Peas." The lecturer, who is an expert on this subject, gave some very useful hints, and explained in detail several important operations. At the conclusion of the discussion a hearty vote of thanks was accorded Mr. Christy.

WARGRAVE AND DISTRICT GARDENERS' ASSOCIATION.

A FORTNIGHTLY meeting of the above took place on Wednesday evening, November 4, when a very interesting paper on "Spring-flowering Bulbs Under Trees" was given by Mr. A. Rogers, of Messrs. Waterer, Sons and Crisp's Nurseries, Hare Hatch, Wargrave. He detailed such points as time of planting, preparation of the ground, methods of planting, and the best varieties to use. The following were among the various bulbs mentioned: Alliums, Anemones, Chionodoxas, Crocuses, Winter Aconites, Dog's-tooth Violets, Fritillaries, Snowdrops, Muscaris, Hyacinths, Scillas and Ornithogalums. A good discussion ensued and much useful information was imparted. A vote of thanks was accorded Mr. Rogers and carried with acclamation.

ROYAL HORTICULTURAL SOCIETY OF ABERDEEN.

THE annual meeting of this society was held the other evening. Parish Councillor Simpson, vice-chairman, occupied the chair. The annual report was submitted and approved of. It showed a credit balance of £27 1s. 10d. The chairman remarked that the membership was showing a falling off, and made an appeal to the members to endeavour to secure accessions to their number. The financial position of the society was still good, and the members had reason to be gratified with this. Mr. A. Robson, who seconded the adoption of the report, urged the desirability of adding to the reserve fund. On account of there having been no show held this autumn, it was resolved to continue the present office-bearers and directors. In room of Mr. A. M. Cocker, who has retired, Mr. James King, The Gardens, Balmagask, was appointed a director.

THE GARDEN.

No. 2245.—VOL. LXXVIII.

NOVEMBER 28, 1914.

NOTES OF THE WEEK.

National Dahlia Society's Annual Meeting.—The annual meeting of this society will be held on Monday next, the 30th inst., at the Hotel Windsor, Victoria Street, Westminster, at 4 p.m. It is hoped that as many members as possible will attend.

Roses in Yorkshire.—To meet the wishes of a number of our readers who cultivate Roses in Yorkshire and other Northern Counties, we have arranged with a well-known amateur grower to write three articles giving his actual experiences in Yorkshire. The first of these articles will appear next week, and the others in our issues dated December 12 and 19 respectively.

A Rare Yellow Rhododendron.—Although *Rhododendron campylocarpum*, a flower-truss of which is illustrated on this page, was introduced to this country from the Himalayas as long ago as the middle of the last century, it is still a comparatively rare plant. It is difficult to understand why this is so, because when in flower at Kew, usually during April, it attracts more attention than any other species, probably on account of its sulphur yellow flowers. Although quite hardy in the London district, it is doubtful if it would do well in colder localities, but anywhere in the Southern or Western Counties it ought certainly to be grown. It appreciates peaty soil free from lime, such as is afforded for Rhododendrons in general.

A Red Rose for Autumn.—Although not so free-flowering as some of the Hybrid Tea Roses, the Hybrid Perpetual variety *Commander Jules Gravereaux* is so good as to warrant attention from those who appreciate blooms during October and the early days of November. It makes a free, vigorous bush, and the large, fragrant flowers are of such a brilliant shade of red as to render them very conspicuous even on a dull day. They are of rather loose, semi-double character, a fact that doubtless has much to do with their opening well so late in the season. This brilliant Rose was raised by Croibier, and first put into commerce in 1908.

A Beautiful White-Stemmed Bramble.—One of the most attractive plants outdoors at Kew just now is the new white-stemmed Bramble named *Rubus giraldianus*. A colony of plants may be seen near the Pagoda, which forms such a prominent landmark in the district. The

stems of this Bramble are 6 feet or rather more in height, somewhat branched and very white. Now that flowers and most of the foliage have gone from other shrubs, the glistening white of this Bramble is most pleasing. It is a native of China, whence it was sent to this country a few years ago. *R. thibetanus*, though not quite so white as the foregoing, is also good, and is a native of the same country. Beyond good soil and the cutting away annually of the old wood and the weakest of the new, these Brambles call for very little attention.

The Perpetual Flowering Carnation Society's Show.—Undeterred by the war, this society is

and their friends free of charge. In connection with the show a conference will be held at 3 p.m., when Mr. M. C. Allwood will read a paper on "The Cardinal Points of Successful Carnation Culture Under Glass," followed by Mr. A. Harris, who will read a paper on "The Construction of Greenhouses for Carnation Culture."

Maize Cobs Malformed.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. W. C. Worsdell showed Maize cobs brought from Nyassaland by Mr. E. W. Davy, one of which had three or four narrow lateral cobs arising from the base and growing apparently in the axils of the lower bracts; the other was curiously fasciated at the apex. The latter was particularly curious, as the common view of the Maize cob is that it arises by fusion of several axes, and it might have been expected to exhibit the fasciation throughout its whole length.

A Good New Single Chrysanthemum.—When visiting Finsbury Park a few days ago, we were very much interested in a new single Chrysanthemum that the genial superintendent, Mr. F. Wright, informed us is named *Eastgate Gem*. It makes a dwarf, compact plant, not more than a foot high, and each shoot is studded with the dainty, bright pink, single flowers. These are of medium size, of good form, and each has a slight white band surrounding the yellow disc. It is used as an edging to a central bed of larger and taller varieties in the show-house at Finsbury Park, and for that purpose is ideal. When obtainable from nurserymen, we anticipate a brilliant future for this useful and charming new-comer.

The Pyracantha as a Shrub.—We were also interested in the large bushes of *Crataegus Pyracantha* that

are growing by the Manor Gate at Finsbury Park. Usually this handsome berried shrub is grown as a wall plant, where it is certainly very effective, unless the wall happens to be a red one; but to see it at its best it should be grown as an ordinary shrub in the border. The plants at Finsbury Park have been in their present situations for some years, and now measure as much as 10 feet in diameter. Although not fruiting so freely this year as we have seen them on previous occasions, there are sufficient berries present to indicate what a beautiful shrub it is if grown in this way.

RHODODENDRON CAMPYLOCARPUM, A BEAUTIFUL YELLOW-FLOWERED SPECIES FROM THE HIMALAYAS.

holding its winter exhibition on Wednesday next, December 2, at the Royal Horticultural Society's Hall, Vincent Square, Westminster. A good show is anticipated, and it is to be hoped that it will be well patronised by the general public. Although the society has suffered in the way of reduced subscriptions, the committee is putting a bold face on the matter by announcing that all the net proceeds of the show will be given to the Belgian Relief Fund. In addition, most of the flowers will be sold for the benefit of the same fund. A further concession to our much harassed Allies is the admission of Belgian horticulturist

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Echium callithyrsum at Bosahan.—Sir Arthur Vivian, whose charming gardens at Bosahan, Cornwall, were described and illustrated in our last issue, sends us the accompanying illustration of *Echium callithyrsum* growing at Bosahan. The plant was given to Sir Arthur in a small state in a pot about three years ago, and during the past summer produced thirty-eight fully developed spikes of its charming blue flowers. It is a native of the Canary Islands, and in the Scilly Isles often attains a height of 10 feet to 15 feet. Unfortunately, it is only hardy in the South-Western Counties of England, and possibly the warm localities of Scotland.

A BEAUTIFUL PLANT OF *ECHIMUM CALLITHYRSUM* IN SIR ARTHUR VIVIAN'S GARDENS AT BOSAHAN.

Buddleia Colvillei Flowering.—Our *Buddleia Colvillei*, which reached the b'ooming age three or four years ago, has this year for the first time thrown two heads of bloom a second time. One is now in flower. I may state we had had all the old blooms carefully cut off. It is fully exposed to the sea winds and is grown without any protection. C. M. TRESTRAIL, Southdale, Clevedon, Somerset.

Carrots Sown in November.—The seed catalogues and the directions on seed packets mostly tell us to sow the seed of Carrot in the spring, but for many years I have sown seed of one of the early varieties broadcast in a large frame about the middle of this month. From this sowing we pull delicious little early Carrots quite three weeks in advance of the outdoor crop, and at that season young, tender cooking vegetables are valuable indeed. Carter's Long Forcing Carrot is the best for the purpose.—F. H. C.

Escallonia montevidensis.—In reference to your query on page 499 of THE GARDEN regarding the hardiness of this splendid autumn-flowering shrub, it may be of interest to state that it succeeds in the open in the more favoured parts of Wigtownshire. About the end of September, when visiting that interesting garden belonging to Mr. Carrick-Buchanan, Corsewall House, Stranraer, where so many of these tender and interesting plants flourish in the open, I saw this growing freely in the open border and just beginning to open its panicles of white flowers. This is certainly a species worthy of more extensive cultivation in the milder parts of the country or near the sea, where these South American shrubs flourish remarkably well, and all grow freely in ordinary well-drained garden soil.—R. FINDLAY, Logan Gardens, Stranraer.

Finger and Toe Disease in Green Crops.—Your correspondent Mr. J. Crook, pages 552 and 553, issue November 14 of THE GARDEN, is quite right in stating that deep trenching of the soil will be helpful in checking this disease. It will not act as an infallible remedy. For a period of ten years I had charge of a large garden in which nearly two acres of winter greens had to be grown on the same plot year after year. The ground had been so cropped for many years previously, as the garden dated from 1717. Club-root was very bad when I took charge, so I had two pecks of agricultural salt and three pecks of unslaked lime per square rod trenched in every year, and then the plants (in a very young state) were planted. Also earthing-up, every autumn or in late summer, was done, and trouble from club-root ceased. It is important that seedlings be raised in fresh quarters every year.—G. G.

Chionodoxa sardensis, Stachys lanata and Apple Lane's Prince Albert. I was delighted to find in THE GARDEN, page 555, a fellow admirer of *Chionodoxa sardensis*. It is a dainty little jewel of a flower, charming in the garden, where every single spray of its pure and vivid colour tells, and even more delightful indoors at closer view in clear cut-glass vases. I was also pleased to see the photograph and note on page 543 concerning *Stachys lanata*. This beautiful foliage plant is so easy to grow and yet apparently so little known. I have often wondered that it is not used for bedding on a large scale. It makes a most excellent border to scarlet *Geranium* or to masses of any pink or yellow flowers. It gives less trouble than almost any other edging, requiring only to be trimmed occasionally and replanted every second or third year. When

used as foliage edging, it should not be allowed to flower. I can confirm from my own experience the excellence of Apple Lane's Prince Albert, illustrated on page 555. I have grown it for several years, and find it the best cropping, cooking and keeping Apple in my garden (where I grow some thirty varieties). No other Apple combines so many good qualities. It is, indeed, not the "Prince" but the "King" of cooking Apples, and really might now well be renamed King Albert in honour of our gallant Royal Ally. In addition to its practical merits, it has the loveliest of all Apple blossoms, and would be worth growing for its flowers alone. I plant May-flowering Tulips Striped Beauty and von Jehring beside my bushes, and these together form one of the prettiest pictures in my garden in May.—ANNE AMATEUR.

Mildew-Proof Roses.—The article by "Somerset" in your issue for October 31 was a very timely one, and should be taken seriously to heart by raisers of new Roses. I readily admit it is not an easy matter to deal with, inasmuch as hybridisation seems to encourage mildew rather than the reverse. Of course, some may say, "Yes, that is so if proceeded with upon the ordinary lines; but surely raisers can break away from the beaten track and strike out upon some other." I have two Roses to name that I venture to say will soon be in every garden, for their freedom from mildew will make them extremely popular. Both are the creations of that marvellous hybridist M. Pernet-Ducher, and are of the new group of Pernetiana Roses, a group to which we may look for many others with like characteristics. One is named Cissie Easlea. It is flowering now most beautifully, and its rich saffron yellow blossoms are certainly the loveliest among late autumn Roses. The foliage is glistening, of a large size, almost as massive as Camellia leaves. The wood is of a brownish mahogany colour, a delightful contrast to the flowers. A splendid feature of this Rose is the width of the erect clusters. I have had some with a spread of fully 18 inches. A lady looking at this Rose on November 4 thought it was Lady Hillingdon, so rich were its opening buds; and it is wondrously free-flowering. I can well believe what Mrs. Farmer wrote recently

that this variety was one of the best at Christmas time last year. The other beauty is Louise Catherine Breslau, which was depicted in the coloured plate issued with *THE GARDEN* for October 10. Here, again, we have glorious 'cathery foliage, a joy to look upon; and what a colour are its flowers—coral red, shaded chrome yellow, open flowers shrimp pink and copper. The blossoms lack refinement of form, but this is amply atoned for by their lovely colour. Anyone wishing to plant beds of unique-coloured Roses could not select any kinds more suitable, and there will be no terror of fungoid blemishes next season, for, strangely, they are even immune from red rust and black spot, diseases to which some of the Pernetianas are rather prone. I need not name Arthur R. Goodwin and its fine sport J. F. Barry, also of this tribe. The former is so well known and should be in every collection. I am sure J. F. Barry will be an acquisition, and I congratulate Mr. Piper in securing such a fine sport. I quite agree with Mr. Rigg in his remarks regarding Lieutenant Chaure. It is splendid, and I am advising all who ask me for a good free-blooming red Rose to plant it. It might almost be described as a dwarf Hugh Dickson, except that there is not quite so much of the scarlet hue. It is evident that locality and soil conditions have a deal to do with mildew or its absence, for I notice "Cheshire" extols the merits of Mme. Ravary, Caroline Testout and Mme. Abel Chatenay as being immune from mildew, whereas "C. Ambrose" brands them as sinners as regards mildew. There are a few of the true Teas especially noteworthy as being free from mildew. One of the best is Mme. Antoine Mari. It is a pleasure to look upon a mass of this Rose at any time, and with me it is almost evergreen. Then there are G. Nabonnand and its cream sport Peace; the latter all should grow, if only for its beautiful name. Anna Olivier and its sport Lady Roberts are also splendid. I really think mildew is hereditary, more especially upon the female parent's side. Lieutenant Chaure, already alluded to, was raised from Liberty x Etoile de France. This latter is a terror for mildew, inherited from Fisher Holmes and Mme. Abel Chatenay, its parents; but Liberty is, with me, free, and, as Mr. Rigg says, Lieutenant Chaure is free from the pest. I have no information as to the parents of Mrs. George Shawyer, but this Rose has been shockingly covered with mildew this autumn. Undoubtedly it is the thick, Holly-like leaved Roses that escape the fungus, and therefore the efforts of raisers should tend towards employing such in their cross-breeding. I am hoping that from Cissie Easlea, Louise C. Breslau and others we may obtain a good mildew-proof race, and Cissie Easlea seeds quite freely here.—**DANECROFT.**

The correspondence on this subject is very interesting. I have not seen a single variety that is quite free from mildew or can be relied on to be immune. Varieties possessing smooth leaves are certainly freer than those with rougher surfaces. Newly planted Roses are freer than those long established in a bed. Those in open quarters are freer than others in draughty places and on walls in hot positions. Plants in shallow soils where the roots get very dry at times suffer more than those growing in a deep loam which is more consistently moist. In my experience the above facts have always stood out prominently. I wonder how much mildew we owe to the dry, unrotted litter found round the roots in the soil!—**SHAMROCK.**

REGELIO-CYCLUS IRISES.

EARLIER in the year (see the issue of *THE GARDEN* for July 4) I had something to say in respect of this fascinating hybrid set, and promised at a more seasonable moment for planting to refer to them again. That time is now with us, and the moment being opportune and the soil in good condition, I will endeavour to redeem the promise then made. Those who are interested in these flowers or would like to make their acquaintance should turn up *THE GARDEN* for June 13 last, where will be found a lifelike illustration of one of the best of them and an interesting communication by the Rev. J. Jacob.

In my previous note I recorded both my successes and failures with these Irises, and by a reference thereto it will be seen that the latter were obviously the outcome of a desire to make of them a permanent success without lifting or special treatment. The successes were equally due to following a rule of thumb method of culture—that, indeed, laid down by Mr. Thomas Hoog (of Messrs. C. G. van Tubergen), Haarlem, through whose insight and enthusiasm the group came into being. This remarkable hybrid set has been evolved from the Oncocyclus and Regelia Irises, and those who have had the least experience of the former—the "impossible Cushions" as they have been called—will realise that the new race is not to be trifled with if success is to be assured. At the same time it must be distinctly stated that the difficulties are not insuperable.

On the other hand, these moderns, while embracing much of the fascinating beauty of the Cushion Irises, have also inherited not a little of the perennially inclined, genialy disposed Regelias, which renders them so much more amenable to cultivation. In a word, they are characterised by hardiness, free growth and flowering, a flower beauty only surpassed by the Cushions themselves, and cultural requirements of the simplest character within certain limits. Apart from these good attributes they occupy a place in the floral chain of the genus which no others have occupied half so well, a fact which should appeal to all lovers of choice flowers. They are practically with us from mid-April to mid-May.

Their Cultural Needs.—I have said that within certain limits this is of the simplest. Essentials in the case are briefly these: A rich, light, loamy soil, one freely charged with lime rubble for preference, perfect drainage, and a long annual rest such as is only afforded by lifting and drying each year. This last condition—this immunity from the excitability of soil influences—despite the obvious evidences of the plant's inclination to grow, is, perhaps, the most important item of all, since it is the continuity of the secondary or early autumn growth which it is so desirable should be restrained till the vicissitudes of the winter season are past. That accomplished, all else is plain sailing. To cover with frames or lights with the same idea of rest in view is not half so good, and, as I have proved to the hilt, brings failure in its train in the course of a couple of years. To ensure this complete rest the rhizomes should be lifted each year in July, shaken free of soil, and stored in an airy place in shallow trays till October, a course of treatment similar to that meted out to a choice lot of Tulips.

The Best Planting Season is October and November, when it will be seen that the plants are beset with sturdy half-inch-long shoots about the main or central ones, and that the root-fibres, in spite of a three months' enforced absence from the soil, show but little, if any, signs of shrivelling. Contrary to custom, these Irises appear best—as the subsequent growth clearly demonstrates—if the rhizomes are planted 2 inches deep, and it is a protection to the shoots, which incline naturally to push early through the soil. These, then, in very brief are the essential needs of these plants, and the measure of their appreciation will be also the measure of their ultimate success.

Varieties.—At the head of the poll I place Charon (a study in old gold and bronze, and indispensable), while Mars (rosy violet throughout and big black blotch), Isis (ruby red), Artemis (rose and grey), Jocaste (satiny white and violet), Eucharis (somewhat suggestive of the lovely Cushion Lorteti), with Psyche, Hera, Luna, Eurydice, Una, Felicitas, Medusa and Irene are others which impel admiration by their infinite grace and charm. **E. H. JENKINS.**

ROOM PLANTS IN WINTER.

MANY plants that have succeeded fairly well in the dwelling-house during the summer and early autumn months begin, when winter sets in, to lose their freshness.

Of course, one looks for this in the case of plants of a soft-wooded character, but when such subjects as Palms, Araucaria excelsa, the hardier evergreen Ferns, and even Aspidistras look more or less unhappy, the cause needs seeking.

Causes of Failure.—There are several reasons that may be put forward for this, but one of the most likely causes of the plants being affected is that with the far greater number of fires, and the increased use of lamps or gas for the purposes of illumination, the atmosphere is rendered much drier than it was. This condition of things is very detrimental to plant-life, and consequently the plants soon show the effects thereof. The best lighting medium for the welfare of plants is electricity, and the worst, gas. The exceedingly dry atmosphere against which we have to contend also causes the soil in the pots to dry as quickly as, or perhaps even in some cases quicker than, in the summer, though, of course, in this respect the condition of the plants, the requirements of the different individuals and their position in the room all play an important part in the matter.

A question put perhaps more frequently than any other is, "How often should I water my plants which are in the window or elsewhere in the room?" This question is easily asked, but absolutely impossible to answer. Take, for instance, a Palm growing in a comparatively small pot. Around the bottom of this the stout roots whence the principal nourishment is derived are coiled. Under such conditions it is almost impossible to overwater it, whereas another one in a larger pot, and consequently a greater mass of soil perhaps unpenetrated by roots, would be killed by the same treatment.

Repotting.—A mistake very common among the uninitiated is that as soon as a plant appears

DOUBLE-STEMMED CORDON PEARS. THESE ARE EXCELLENT FOR SMALL GARDENS AND MAY BE PLANTED NOW.

somewhat sickly it is looked upon as wanting a larger pot, whatever be the season of the year. Even if it would be benefited by an increased size of pot, the operation of repotting should not be carried out after August; indeed, the months of April, May, June and July are best for the purpose, as there is then ample time for the new roots to take possession of the fresh soil before the winter. Such being the case, if plants at this season appear to be underpotted, the better way will be to wait till April before disturbing them at the roots.

When to Give Water.—As it is impossible to state any definite period when room plants should be watered, a few words of advice may be given on this point. In the first place, the soil must be allowed to get dry before watering, and then enough water should be given to thoroughly moisten the ball of earth. By dry it is not meant that the soil must be parched up so as to injure the plant, but rather that it is in that condition which a careful observer will at once see as likely to be benefited by a good watering. Above all things, avoid giving little drops frequently, as this will undermine the constitution of plants as well as mankind. When a plant needs watering, the better plan will be to take it from the room and stand it in a pail of slightly tepid water at such a

depth that the rim of the pot is covered. When the water has percolated through the entire ball of earth, which may be ascertained by the air bubbles ceasing to rise, it should be taken from the pail, allowed to drain, and then be taken back into the room. On no account, either in summer or winter, must stagnant water be allowed to stand in the jardinières in which the plants are placed.

Cleanliness.—With the dry atmosphere there is always a certain amount of dust, and to keep the foliage of the plants as clean as possible is a very important matter. Such subjects as the Aspidistra, India-rubber Plant and Palms of different kinds, whose leaves are smooth and of a firm texture, may be readily kept clean by occasionally sponging with lukewarm water. On the other hand, such subjects as Ferns, whose foliage is more intricately divided, collect the

dust to a greater extent than the smooth-leaved plants, and are also more difficult to clean. The better way is to take advantage of a mild day (and there are many such during the winter) to give them a syringing. On no account, however, must sponging or syringing be done during severe frost, while watering should then, if possible, be avoided, or, if absolutely necessary, it should be done in the morning so as to allow any superabundant moisture to dry up.

Treatment in Cold Weather.—Another very important matter during sharp, frosty weather is to bear in mind that the greatest cold is, as a rule, experienced in the night when the fire is out, and consequently the temperature of the room falls rapidly. The coldest part is, of course, in the window, where most of the plants are usually kept; and in order to make all safe when there is any reason to expect a severe night's frost, the plants should be removed from their more exposed position to the centre of the room, where, arranged in a close group and covered with a few newspapers, they will be safe. When possible, however, they should be stood in the window, so as to obtain the full measure of light which is so essential to the welfare of plants in general.

H. P.

CORDON FRUIT TREES FOR SMALL GARDENS.

ALTHOUGH cordon fruit trees are undoubtedly grown much more extensively than they were ten or fifteen years ago, amateurs generally do not seem to appreciate anything like to the fullest extent their value for small gardens. This is rather curious, because they are undoubtedly the type of tree *par excellence* where space is limited, and when they are once furnished with fruiting spurs are so simple to manage that the veriest tyro could scarcely make a mistake with them. Cordon trees may consist of one, two, three, four, or even more stems, each of which it is desirable to have covered with sturdy fruit-spurs from as near the ground as possible to the top. Generally speaking, however, those with only one, or at the most two stems are the most serviceable, those having more usually being chosen for some special position, such as a pillar or buttress to a wall, as shown in the illustration on the next page.

Where to Grow Cordons.—Although this simple type of fruit tree is usually regarded as highly desirable for growing against a wall or fence, such positions are by no means essential to their well-being. They will do almost, if not quite, as well fastened to wires or other supports beside the pathway in the garden, where they take up but little room and provide a good supply of the very best quality fruit. So as to get a longer stem than would be obtainable if planted upright, single and double cordons are usually planted sloping at an angle of about 45°, and preferably from south to north, so that they get all the sun possible. When trained to a wall, a slope in the direction named cannot, of course, always be provided.

Planting.—This can be carried out at any time from early November until the middle of March, providing the ground is not sodden or frozen hard. Young trees can be obtained from any of the fruit nurserymen advertising in *THE GARDEN*, and the earlier during the period named they are put in the better. The soil must have been previously well prepared by deep digging and the adding of some well-decayed manure to the bottom spit. It is not advisable to fasten the trees to wall, fence, wires or other supports for two or three weeks after planting, as, if the soil settles very much, the roots will be drawn partly out of the ground. If supports are necessary to prevent the trees being blown about in the meantime, a few rough stakes thrust well into the ground, and the trees tied lightly to them, will answer the purpose.

Pruning.—As already hinted, this is a very simple matter indeed. The kinds of fruit most suitable for growing as cordons are Pears, Gooseberries, Red and White Currants, and most varieties of Apples. These will all produce fruit on short spurs or side growths, and it is to the securing of these growths that the cultivator must pay attention. Usually when cordon trees are bought from the nursery they have two or three sets of spurs near the base, the remainder of the main stem being of the current year's growth. The spurs that are there may be left alone and the main shoot cut back to a good plump bud situated from a foot to 18 inches from the uppermost spurs. Early next summer all the dormant buds in this main shoot will

produce growths, and about the end of June all the side or lateral ones should be cut back to within four buds of their bases. The main stem or leader will, of course, be allowed to grow unchecked. Any shoots produced from the spurs must be cut back in the same way as advised for side shoots on the upper part of the main stem. If secondary side growth is made, this should be cut or pinched back close to where the cut was made in June. In the winter these side shoots or stumps are cut to within two buds of their bases, *i.e.*, two of the four buds left at the summer pruning are cut away. This is the way that fruit-spurs are made. When the main stem has reached the desired distance and is covered with fruit-spurs, all that is necessary is to cut in all side shoots at the summer pruning and reduce the stumps at the winter pruning. Owing to the hard cutting, it is not advisable to grow Cherries or other stone fruits as cordons, though in many localities Plums are grown in this way and seem to do very well. The fruit obtained from cordon trees, owing mainly to the full exposure that it gets, is usually of the very best quality, highly coloured, and easily protected from birds by means of old fish-netting.

A. B. ESSEX.

SOME GOOD SHRUBS FOR FORCING.

THE time has now arrived when those who wish to make displays of forced shrubs for greenhouse decoration in spring should commence bringing their plants into a little heat, for it is better to bring them into flower gradually, by allowing two or three weeks longer for forcing, than to subject them to excessive heat in the hope of flowers appearing quickly.

Forcing plants, it must be remembered, is a source of some considerable amount of work and expense; consequently it is advisable that really good examples only should be requisitioned—not, as sometimes happens, the leavings of a batch of plants which were not considered good enough for outdoor planting or half-worn-out shrubs from a border. In some nursery gardens, more particularly Continental ones, a speciality is made of shrubs for this purpose, and really first-rate material may be obtained at a moderate price. When plants are grown specially for the work, little but flowering wood is found, for all weak shoots are removed to throw all possible strength into the principal branches. Moreover, they are not allowed to flower and so waste a certain amount of energy in the intervening time between their propagation and the period when they are ready for the forcing-house. Special attention is given to the ripening of the wood, and in some instances the large roots are cut about the end of August to check growth and facilitate ripening.

Assuming that such plants have been obtained and that they are now in pots plunged out of doors, it is as well to anticipate frost by scattering leaves, hay or Bracken among them in order that they may be lifted at will, even during an extended period of frost. Should the plants not have been procured, however, no time should be lost in obtaining a supply, and if they can be had established in pots, select them by all means.

Plants which are forced early are naturally weakened more than those which are brought into

blossom nearer the normal time. For this reason the owner has to consider whether it is better to throw the plants away as soon as the flowers have fallen, or whether it will pay him better to find them house-room for a while and then plant them out of doors for a season. The cheaper kinds are often not worth keeping, but such as double-flowered Peaches, Cherries and *Wistaria sinensis* should be retained; in fact, the *Wistaria* and some of the double-flowered Cherries may be grown in pots and forced successfully several years in succession. *Rhododendron sinense*, better known perhaps as *Azalea mollis*, is a plant which does not pay for forcing a second year, while it usually takes several years to become strong enough to force a second time. Really fine plants carrying forty or fifty buds may often be purchased at from 9d. to 1s. 3d. each, and when once forced may either be planted out permanently or be thrown away. Evergreen *Rhododendrons*, again, rarely give satisfactory results if forced two years in succession, but a year in nursery quarters is often enough to enable them to pull themselves together and set sufficient buds to warrant their being forced again. The *Lilac* is another shrub which cannot be forced profitably in two successive years, while it pays to let it have two years' rest between the periods of forcing. The most satisfactory results are obtained by cutting forced *Lilacs* well back after flowering, then allowing but a few shoots to mature, the remainder being rubbed off while quite small. The succeeding year a few shoots only are again left to mature, which allows the maximum of strength to go to these shoots to form well-matured wood and buds.

In most kinds good, vigorous shoots are required on plants which are to be forced, and this is particularly the case with *Spiræas*, *Deutzias*, *Forsythias*, and the double-flowered forms of *Prunus japonica*, *P. triloba*, *Kerria japonica* and Peaches; but in a few instances stunted growth proves most productive of flowers. The best example of this is *Wistaria sinensis*, for it never blossoms better than from stunted spur-like shoots.

The size at which shrubs may be forced depends on the size of the forcing structure, for though, usually, comparatively small ex-

amples are used, fully developed specimens of *Guelder Rose*, *Lilac*, *Forsythia suspensa*, *Rhododendrons* and many other kinds may be requisitioned. Should large plants not be required for future planting, but can be thrown away as soon as the flowers are over the roots may be reduced to a moderate extent to save pot room, or the balls may be bound up in mats and stood in baskets or boxes during the time they are indoors. It is always necessary to remove forced shrubs from the forcing-house to a cooler structure as the flowers begin to open, or the flowering period will be a very short one. Flowers which fall quickly, such as *Azaleas*, may be made to remain on the plants for a fairly long period by fixing them with floral gum, which may be obtained from any seedsman or horticultural sundriesman.

It is only necessary to mention a few of the many shrubs suitable for forcing—others will readily suggest themselves to the minds of those who wish to force a larger collection: *Spiræa arguta*, *S. van Houttei*, *S. confusa*, *S. prunifolia flore pleno*, *Deutzia gracilis*, *D. parviflora*, *D. Lemoinei* and all the *gracilis* varieties and hybrids, *Forsythia suspensa*, *Prunus persica flore pleno*, *P. serrulata*, *P. triloba*, *P. Pseudo-cerasus*, *P. japonica flore pleno*, *Pyrus floribunda*, *P. Scheideckeri*, *Wistaria sinensis*, *Neviusia alabamensis*, Japanese Maples, *Weigela* or *Diervilla* *Eva Rathke* and other kinds,

A PEAR TREE TRAINED TO COVER A BRICK PILLAR

Viburnum Opulus sterile, *V. tomentosum plicatum*, *Robinia hispida inermis* and *Rhododendrons*, deciduous and evergreen. All are, however, not suitable. Of deciduous ones *R. sinensis* and its numerous varieties and forms of *R. flavum* and *R. calendulaceum* are the best, while the earlier-flowering evergreen kinds answer more satisfactorily than the later ones. In addition to these there are many other kinds, such as *Magnolias*, *Hydrangeas* and *Kerrias*, which may be pressed into service. W.

THE INDIAN BEAN.

(*CATALPA BIGNONIODES*.)

THIS is one of our most valuable flowering exotic trees, there being nothing so showy among the larger-growing trees which blossom during July and August. There is a further period of interest, if not of exceptional beauty, during late autumn and early winter, when the trees are laden with long, slender, Bean-like fruits. *Catalpa bignonioides* forms a round-headed, wide-spreading tree 30 feet to 50 feet in height, with large cordate leaves and white flowers $1\frac{1}{2}$ inches across, spotted with purple and yellow in the throat. These are freely borne in large terminal panicles, rather suggesting the Horse Chestnut. A few of the flowers mature fruits, usually from about four to a dozen in each panicle. During a fine autumn the trees are much more heavily laden than when it is wet and cold. The long, slender, pendent fruits vary from 6 inches to a foot in length, occasionally more, and are rather thicker than a pencil. They hang on the trees for some time after the leaves have fallen.

The Indian Bean Tree is a native of the Eastern United States, and was first introduced in 1726. Though *C. bignonioides* is the better-known name, *C. syriaca* is still used by some cultivators. It is a very good tree for towns, there being several fine specimens in and around London. Coming from the Eastern United States, it will be readily understood that the best trees in this country are usually found as lawn and park specimens in the South and West of the British Isles. The best method of propagation is by seeds, though cuttings will root in a frame during the late summer. This year a medium-sized tree, growing near the Temperate House at Kew has produced a very heavy crop of these curious pods, so well shown in the accompanying illustration, and has been a source of much interest to visitors. This tree is situated by the canal beds at the end of the Temperate House nearest King William's Temple, and even as late as the 16th inst. was carrying a great many fruits. It would be interesting to learn whether trees growing in other parts of the country have fruited well this year. We should be glad to hear from any reader, particularly in the colder parts of the country, who has noticed seed-pods.

PREPARING A ROCK GARDEN FOR AUGUST AND SEPTEMBER.

A GARDEN is a spot to be enjoyed all the year round, but there are some unlucky people who have to "crib, cabin and confine" their gardening instincts within the limits of the holiday months of August and September, and in August, alas! even Nature herself inclines to take a little siesta. Then the rock garden more especially loses some of its attraction unless we can think out some flower-scheme for that particular season; for while there are

below the tall, upright spikes of fringed white flowers. This *Pavia*, with hardly the characteristics of even a dwarf tree, for it does not exceed 8 feet or 9 feet in height, spreads by suckers and requires a certain amount of room, but is well worth the attention of those who have a suitable position and space to give to it. Another August-flowering shrub is the evergreen *Olearia Haastii*, one of the New Zealand Daisy Bushes, which covers itself with heads of closely packed white flowers, not unlike those of *Milfoil*. This appears to be quite hardy everywhere, and would not be out of character in some aspects of rock gardening; but to prevent its becoming scraggy, it should be trimmed a little into shape after flowering. *Caryopteris Mastacanthus*, a pretty blue-flowered shrub about two feet high, which also flowers late, might be used with advantage to break the level of a low rocky bed.

Among true mountaineers we may place in the forefront the Swiss *Eryngium alpinum*—"la reine des Alpes" on M. Correvon's authority—for, after all, not all alpine crouch before the blast. *E. amethystinum* is a very similar Dalmatian species, though more straggling. Both grow easily in dry soils and are delightful plants, lasting through August and well into September. *E. oliverianum*, the species generally seen in English gardens, is taller and more vigorous in habit than either of the preceding. These are becoming rare even in their own haunts from the ruthless snatching of tourists—all the more reason, therefore, for their preservation in gardens. Then there are several autumn-flowering *Gentians*. In a moist bay at the foot of rocks—often an accessory of an important rock garden—where the soil is fairly deep, *Gentiana Pneumonanthe* and its still more beautiful white variety will be quite happy and have no objection to sun and breeze. The Willow *Gentian* (*G. asclepiadea*), on the contrary, prefers a cool spot facing north and reaches a height of 18 inches or more. It grows naturally in damp, rocky woods, but is not tied and bound to such spots under cultivation. *G. Andrewsii*, though not so ornamental as some others, and best in bud, is, like the above, another late-flowering lover of damp spots. A charming *Gentian* of lesser dimensions, *G. ciliata*, with fringed flowers of a delicate soft blue, which grows abundantly by rocky waysides in Luxembourg and Germany, likes a drier position and does well between stones. A Himalayan species, *G. Kurroo*, which has

SEED-PODS OF THE INDIAN BEAN, *CATALPA BIGNONIODES*. A TREE IS FRUITING VERY FREELY NEAR THE TEMPERATE HOUSE AT KEW THIS YEAR.

plenty of bold and handsome plants, with flowers of red and yellow shades innumerable, for the perennial borders, the buxom vigour of these would be quite out of place among lowlier rock plants. It may be possible, perhaps, though not very easy, to suggest some available material.

As a rule a rock garden is not immediately in evidence, therefore no apology need be offered for calling attention here to a fine August-flowering shrub, or dwarf tree, which might very well find a position on the way to it. *Pavia macrostachya* is then very beautiful, though strangely seldom met with. It is a kind of etherealised Horse Chestnut, with graceful, fingered leaves drooping

sky blue flowers, nearly two inches long, blooms in August and September, and is much more amenable to cultivation than it was once supposed to be, growing freely in suitable quarters, where it likes to be left alone without disturbance. This species enjoys moist but well-drained peat and loam, and plentiful watering in summer.

Of autumn-flowering *Campanulas* there are not many, but two or three may be mentioned. *C. tommasiniana*, 9 inches to 12 inches high, appears to be a later-flowering variety of *C. waldsteiniana*, so nearly are they allied. The trailing *C. fragilis* and *C. isophylla*, both Italian species, and perhaps not over-hardy in all districts,

are due to flower in August and prefer semi-shade. *C. Allionii*, 3 inches to 4 inches high, though not always easy to manage, comes also in August and is worth trying, as it may go on flowering into September. *C. carpatica* lasts long through the summer, and so does *C. rotundifolia*—the Bluebell of Scotland and as charming as any—but, in thinking of plants for August and September, it is safer to restrict ourselves to those which naturally come into flower during those months, otherwise a little variation in the season may leave us bereft when we most want the rock garden to look its best. It must always be borne in mind, however, that locality, north or south, makes all the difference in time of blooming. The blue-flowered *Cyananthus lobatus*—a Himalayan scion of the same Bellflower order—is very charming where it succeeds, and delights in sandy peat and leaf-mould in a partly shaded position.

For a trailing plant to grow over the face of a rock, another Himalayan plant, *Polygonum vacciniifolium*, may be noted, the rosy spikes of bloom, and leaves often tinged with red in the autumn, being seen to advantage draping the grey surface of the stone. Thymes are always delightful in autumn, and especially the golden form of the Lemon Thyme, which increases in brightness of colouring as the year advances. Snapdragons—wall plants by nature—can be used most effectively in their best forms. Of the same genus, the creeping *Antirrhinum glutinosum*, a true rock perennial, though not a very long-lived one, will spread its little mat of white Snapdragon flowers all through the summer and autumn; and also its near ally, *Linaria alpina*, of brighter colouring, is always welcome, and will sow itself where it is happy.

Probably no upland plants are better fitted to give autumn colour than some of the varieties of Heather and Ling. There is the Cross-leaved Heath (*Erica Tetralix*) for any moist, boggy spot; many varieties of *Calluna* or Ling, for exposed positions; the Scottish Heather (*E. cinerea*); the Dorset Heath (*E. ciliaris*); and the Cornish Heath (*E. vagans*), a very bright and lovely species which must be seen on the moors of Lower Brittany to be thoroughly appreciated—all of these may be pressed into the service to make a Heather garden. Most beautiful of all is the white form of the Irish Heath (*Daboecia polifolia*), which can be freely planted anywhere in Heath soil without fear of clashing colours. The great point to remember is that all of them are the better for a clipping after the flowering season is past, or they are apt to get ragged and lose much of their beauty. Naturally, a sandy peat soil suits them best, but they are not dependent upon it, and these hardy Heaths come in well sometimes where more fastidious plants fail. For example, a rough bank, mostly clay with some sand, much inclined to slip bodily away, and hurriedly shored up with huge water-washed boulders from the bed of a Welsh river—about as unpromising material for rockwork, even of the rudest kind, as could be found—was made quite beautiful by a liberal planting of these brave Heaths.

But there are not many alpenes, strictly speaking, that can be relied upon for late summer and

autumn blooming, and we must fall back upon other types that may not be out of character in the rock garden. *Zauschneria californica* is one of these, and admirable for a position among stones, for it insists on well-drained soil and as sunny a location as can be found for it. The scarlet tubular flowers are well set off by the grey-green of the foliage, and charming when seen in perfection. It appears, however, that two varieties are in cultivation, one very free-flowering, the other just the reverse, which is often the cause of disappointment. Almost everyone, too, would be pleased with the effect of good clumps of the New Zealand Pheasant's-tail Grass (*Apera arundinacea*) for raised positions, especially when the slender, arching flowering stems of shining brown purple are in perfection, as they are in August and September. It grows from 18 inches to 2 feet high here in Sussex, and, considering its merits, is not too well known. The Iceland Poppy (*Papaver nudicaule*), which, though

work is done, when the stems should be cut away. It must be admitted that this *Convolvulus* has a fault, for, like all its tribe, it is apt to encroach; but it never becomes a pest, like those others, and is generally beloved of all who grow it. It likes a warm, sheltered position, and goes on flowering well into the autumn. A longer list might be given if other miscellaneous plants were included; but it is already long enough to show that the rock garden in August and September need not be lacking in flowers.

K. L. D., in *Country Life*.

SEEDLING PINKS FOR WALL GARDENS.

For dry retaining walls there are few more suitable plants than seedling Pinks, those wild kinds, such as *Dianthus deltoidea* and *D. plumarius*, seeds of which can be obtained from almost any seedsman of repute. Apart from the additional vigour that seedlings usually possess, there is

SEEDLING PINKS GROWING IN A DRY RETAINING WALL.

perennial, succeeds almost better treated as an annual, comes into flower from early spring-sown seeds by the end of July, and is at its best when autumn-sown plants are over. The tiny Alpine Poppy is a miniature edition of the same—so botanists tell us—though for garden purposes it is entirely distinct, and does well under similar treatment.

In Northern gardens, *Heuchera sanguinea* will produce its lovely coral spikes at this season. *Viola cornuta*, too, in its improved purple form, is very attractive, and Red Valerian (*Centranthus ruber*), especially in its so-called scarlet form, a plant to be placed on some high point of vantage where it can be seen from afar, is very fine: but all these would come under the head of summer flowers in the Southern Counties. Where a twining plant is wanted, *Convolvulus althæoides*—a slender, silvery-leaved perennial with rose coloured flowers—is desirable, both in leaf and flower, and dies down for the season after its

generally some variation in the colour of the flowers, which, to all except expert alpine plant lovers, and even to some of them, is pleasing. The seed is usually sown in early spring in pans or boxes filled with sandy soil, these being stood in a cold or very slightly heated frame until germination, which may be rather slow, is effected. As soon as large enough the seedlings are pricked off into other pans or boxes, and subsequently either transferred direct to the walls or transplanted into nursery beds, where they stay until the autumn or the following spring. Where seedling Pinks are available now, they may safely be planted in dry walls, providing the roots are disturbed as little as possible. They appreciate gritty loam, and if a little old mortar can be mixed with it, so much the better. Even when not in bloom the glaucous grey foliage of many of these seedling Pinks is very charming, especially during the winter months.

D. D.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Strawberry Plants for Forcing.—If ripe Strawberries are desired early in the year, no time should be lost in selecting the plants and placing them under cover. Well-rooted plants with prominent crowns are best for this purpose, and if worms are present in the pots, these may be destroyed by watering with weak lime-water, which should be given in sufficient quantity to moisten all the soil. The best way to start the plants into growth is to plunge the pots in a gentle hot-bed composed of Oak leaves, which should be trodden tightly together in a brick pit until the top of the bed is within a foot of the roof glass. When the temperature of the bed reaches 70°, the plants may be plunged to the rims of the pots; but care must be taken that the temperature of the bed does not become too high, or the roots will suffer in consequence.

Peach Trees in Late Houses.—These should be pruned and trained with as little delay as possible. Cleanse the house thoroughly and see that the border is in good order. If the roots are near the surface, all that is necessary is to remove an inch of surface soil and replace it with loam and bone-meal. This must be made moderately tight, and if the border is at all dry, give a good soaking of clear soft water.

Cucumber Plants from which supplies are being gathered should be given a night temperature of 70°. Keep the growth well within bounds by frequently pinching the leading shoots. All rough, overgrown leaves must be removed to make room for young fruitful shoots, which should be pinched at the first or second joint beyond the fruit. Top-dress the bed lightly as often as the young roots appear through the soil, and promote a humid atmosphere by frequently damping the walls and floor of the house.

Plants Under Glass.

Propagating Chrysanthemums.—As soon as good, healthy cuttings are available, they should be inserted in small, clean pots of sandy soil and placed in a cool propagating-pit. This ought to be kept quite close until young roots have been produced. Cuttings should be selected from the bases of the plants, and never more than 2 inches long. Care must be taken that the base of each cutting rests on the soil, which should be made moderately firm. As soon as the cuttings begin to make fresh growth, they must be gradually accustomed to light and air until they are removed from the propagating-pit to a more exposed position.

Watering Palms.—All Palms in a healthy condition require a liberal supply of water at the roots, especially when strong fire-heat is necessary to keep the temperature as it should be, as under these circumstances the atmosphere is liable to become too dry. This must be guarded against by frequently syringing the plants and their surroundings, in order to keep insect pests in check. Some stimulants should be applied occasionally to keep the plants in good health.

Salvia splendens.—As these plants pass out of flower, a few of the healthiest specimens ought to be slightly cut back and placed in gentle heat for the purpose of producing cuttings, and these should be inserted in small, clean pots of sandy soil as soon as they are large enough to handle. Slight bottom-heat will be an advantage, and as soon as sufficient roots have been made, the syringe must be freely applied to keep red spider in check.

The Flower Garden.

Violas.—It is not too late to propagate Violas for spring planting, providing the plants were cut back a month ago, for by this time numerous young shoots will have been produced, and when the old plants are pulled to pieces many of the shoots will have formed roots. These should be inserted in sandy soil in frames about a foot from the glass, and may be kept close for a week or two; but when once established, air must be freely given to keep them from becoming drawn. During mild days the lights should be removed with the same object in view.

Antirrhinums.—Young plants raised from autumn-sown seeds which are intended to flower in May and June ought to be pricked into shallow boxes as soon as large enough to handle. After this has been accomplished, the boxes should be placed on a bed of ashes near the glass in a cold pit. Ventilate freely after the plants have become established and do all that is possible to keep them stocky.

Lawns.—Nothing is more detrimental to the appearance of an establishment than a badly kept lawn, occupying as it does a position near the mansion. Frequent sweeping and rolling is necessary during the winter, especially if the weather is mild. A light dressing of decayed horse-manure should be applied to the grass in early winter, and this ought to be frequently brushed in among the grass while the weather is mild. Clip the edgings and do all that is possible to give the place a smart appearance.

The Hardy Fruit Garden.

Sweet Cherries.—The pruning and training of these trees should be pushed forward as quickly as possible. If the young shoots have been carefully stopped during the summer, very little will be necessary now beyond thinning some of the worthless wood from the spurs and cutting back the leading shoots to within a foot of last season's growth. In tying the shoots to the wires, great care is necessary that they are not fastened too tightly, for Sweet Cherries are very subject to canker, and this is frequently the cause. Cherry trees in the open plots or in the orchard should have their branches freely thinned, and young growth be cut back to within a few eyes of the previous season's growth with a view to producing fruiting spurs.

The Kitchen Garden.

Spring Cabbage.—When the ground is in a suitable condition, the surface should be lightly broken up with a hoe and any blanks made up with plants from the seed-bed. The remainder of these ought to be pricked out 4 inches apart, and will make good, strong plants ready to put out in March. From these a good supply should be available in July.

Mustard and Cress.—Make weekly sowings and cover the seeds with sheets of paper. A slightly heated pit is best for this purpose.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

French Beans.—Where ample accommodation is at command, the forcing of these can be carried out almost throughout the season. For ordinary purposes, however, the present will be soon enough to make a start, where these have to be grown in pots. The number of seeds to be sown must be determined by the demand, but it is best to make a small sowing, say, once a fortnight, than to put in a large number at once. Ordinary garden soil, with the addition of some good loam, will suit them admirably. When the Beans are a few inches high, they should be supported by small stakes or twigs, otherwise the result will be a tangle.

Cauliflowers.—The plants that are being wintered in frames need to be frequently examined at this season, and, unless in very severe weather, the lights must be kept open. An occasional dusting of soot or lime will not only ward off slugs, but tend to sweeten the atmosphere.

Potatoes.—If the sets intended for early forcing were put in boxes to start, as advised at the beginning of the month, they should now be sufficiently advanced to be planted. If only a very few are required for early forcing, these could be grown in large pots; but for the most part those planted out in heated pits will be found to give by far the better results. Before planting, fork some leaf-mould into the soil, which will tend to keep the tubers dry.

Lettuce.—Any plants that were left outside on a sheltered border should be carefully lifted with a good ball of soil attached and planted in cold frames. These will be found to come in very handy at a time when salads are at a premium.

Carefully remove all decayed leaves and see that the plants are not overmoist at the roots, which would cause damping.

The Flower Garden.

Shrubs.—In many districts it is necessary to afford protection to some of the more tender trees and shrubs, and if not already done, this should be seen to at once. On no account must any shrub be bound up with mats as if it were leaving the nursery to be despatched on a long journey. This is not only unsightly, but injurious. A few branches of Spruce or Yew tied round will be found to be ample, or for smaller subjects dry Bracken will meet the case. When the weather interferes with digging or turfing, the shrubbery should be gone over, all dead branches cut away, and the whole made tidy.

Rock Plants.—The greatest care should be taken of those choice rock plants that have been transferred to frames for protection during the winter season. When it is remembered that they suffer more from dampness than cold, it will be seen how necessary it is to admit air on all favourable occasions. If in pots, these should be plunged in pure sand, and if planted out the same material ought to be used, with the addition of some powdered charcoal. Look over the plants from time to time and remove all decayed leaves and anything that would create dampness.

Lobelia cardinalis.—Owing to the absence of frost, this plant continued to bloom very late in the season; indeed, it was still flowering here during the first week in November, and the lifting and storing of the roots was delayed in consequence. Any plants still in the ground should be lifted at once and placed in boxes. These are best stood in a frame or shed and kept moderately dry.

Plants Under Glass.

Begonia Gloire de Sceaux.—This fine winter-flowering subject will now be coming into bloom, and should be placed where the atmosphere is somewhat dry. As the plants will have exhausted the soil in the pots, artificial feeding must be resorted to. This may take the form of liquid manure, with an occasional dusting of Clay's Fertilizer.

Poinsettias.—These will now be developing their bracts, and in the case of the most forward, artificial feeding should be discontinued. Those intended for later use may still be given liquid manure. To preserve the blooms in a cut state, the stems ought to be dipped in a few inches of boiling water immediately they are cut.

Campanula pyramidalis.—Although this is more or less hardy in many districts, still, in the Northern Counties, the plants will be all the better for the protection of a cold frame or a late Peach-house. Young plants should be kept growing, and may be potted into 6-inch pots as they are required.

The Hardy Fruit Garden.

Pruning.—As all the trees will now be divested of their leaves, pruning may be proceeded with on all favourable occasions. This work should only be done by a person having a knowledge of the various varieties of trees to be pruned. In the case of bush or standard trees, perhaps all that will be necessary will be the removal of a branch here and there. On the other hand, if young trees have been summer pruned, as already advised, very little pruning will be required.

Fruit Under Glass.

Late-Keeping Grapes.—Grapes still hanging will require to be very carefully attended to at this time, chiefly in keeping the house properly ventilated and examining the bunches for decayed berries. The cutting and bottling of Grapes must be determined by a number of circumstances, chiefly the nature of the variety and the crop the rods are carrying. As a rule, however, all except Lady Downe's and any other very late Grape can with safety be cut and bottled now. Very often rats play great havoc among late-keeping Grapes still hanging. One rat alone will account for two or three bunches in a night. As a precautionary measure, in addition to trapping, a quantity of Furze may be tied round the rods near the ground.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Carnation Pink Sensation.—The sensational aspect of this handsome Perpetual-flowering variety is most probably reflected in the fine proportions of the flower, in which respect as shown it is far away the largest of its race which has yet seen the light. Wedded to this is that tone of pink which sells. We did not detect any perfume in the variety.

Chrysanthemum Meudon.—This is a variety of the exhibition type, a sort of intermediate between incurving and reflexed. The flower-head is deep, well filled and handsome, the pink petals having a silvery reverse. It is good and distinct. The Carnation and this came from Messrs. W. Wells and Co., Merstham, Redhill.

Chrysanthemum Sir Tony.—A single-flowered sort of moderate size and of intense bronze hue, quite a remarkable shade of colour. The distinctly reflexing or drooping floret tips add character and charm to a particularly pleasing variety. From Mr. W. J. James, Farnham Royal.

Odontoglossum crispum Millee.—This handsome variety is characterised by large size, good form, and pure white flowers of great substance tipped with brown on the lip. It is a very striking and beautiful sort. From Messrs. Flory and Black, Slough.

Sophro-Cattleya November.—The sepals and petals are of rich rosy purple hue, very deep and intense, the scarlet-shaded lip adding fire and light to a very beautiful flower. The latter has a distinctly rounded outline. The plant is very dwarf habited. From J. Gurney Fowler, Esq., Brackenhurst, Pembury, Kent.

All the foregoing were shown before the Royal Horticultural Society on the 17th inst., when the awards were made.

THE EDITOR'S TABLE.

Choice Shrubs from Scotland.—Mr. R. Findlay, Logan Gardens, Stranraer, sends from the open flowers of quite a number of choice shrubs that are usually cultivated in the greenhouse. These include *Eupatorium wienmannianum*, *Cassia corymbosa* and two varieties of *Abutilon*. Mr. Findlay writes: "I enclose a few sprays of various greenhouse shrubs cut from the open garden, showing how well these things grow in our mild climate, and these late-flowering shrubs are so valuable in the garden in autumn. The garden at this date is really wonderful, owing to the long time of bright sunshine we have had. *Eupatorium wienmannianum*, a South American shrub, is generally grown as a cool greenhouse subject for decorating or for furnishing a supply of cut flowers; but in the milder parts of the South-West it flourishes freely in the open. The plants under notice have now been in the open for a number of years, and have not suffered to any extent from frost. They are growing in a slightly shaded position and usually begin flowering about the middle of September, and, providing we escape early frosts, continue to do so during October and the greater part of November. This is a most desirable species, with large corymbs of sweet-scented white flowers produced with the greatest freedom. It is probably hardier than it is generally thought, as I saw a fine plant of this flowering freely on a sunny bank in the grounds of Castle Kennedy, which, Mr. Cruden assured me, had no

protection during winter. Cuttings of young shoots root freely if inserted under a bell-glass in early autumn. A sunny bank sheltered from the north and east, with a rich, well-drained loam, seems to suit this useful late-flowering shrub out of doors."

CULTIVATION AND COLLECTION OF MEDICINAL PLANTS IN ENGLAND.

[The following has been recently published as Leaflet No. 288 by the Board of Agriculture.]

(Continued from page 571.)

FENNEL (*FENICULUM CAPILLACEUM*, GILIBERT).

THE cessation of the supply of the fruits of this species of Fennel from the Continent may tempt farmers to try to grow Fennel in this country. Any crop produced is almost certain to sell well. Fennel likes plenty of sun, and is adapted to dry and stony situations, but yields best on rich soil on the stiff side. From 4½lb. to 5lb. of seed are

correct conditions of shade and moisture. Several times the amount of drug now used would be absorbed for making fluid extract of hydrastis and the alkaloids hydrastine and hydrastinine.

Cultivation.—The native home of Golden Seal is in deep, shady nooks in American forests with rich, deep soil full of natural moisture, but not waterlogged. To imitate natural soil conditions, beds should be double dug in autumn, and plenty of leaf-mould or well-rotted peat manure should be dug in during autumn. A second and similar treatment should follow in spring before planting. The beds may be arranged under natural or artificial shade—either under trees or under lattice work. The object aimed at is to protect plants from the heat of the midday sun, and from heavy rain and drying winds. Beds made in orchards and arranged so that the fruit trees shade them at midday would seem adapted for this purpose. The beds could be sunk several inches if deficient in natural moisture. A 2-inch drain with good fall 15 inches below the surface should prevent water-logging on wet soils. Golden Seal has been successfully grown in the shade of Apple trees near Moscow.

VEGETABLES SHOWN BY MESSRS. SUTTON AND SONS AT THE LAST ROYAL HORTICULTURAL SOCIETY'S SHOW. GROWN FROM SEEDS SOWN SINCE THE OUTBREAK OF WAR.

sown per acre. In the mild climate of France the seed is usually sown in August or September, but spring sowing would be necessary in England. The fruit is heavy, and a crop of 15cwt. per acre would probably be obtained. Cutting should be done before the fruits are fully ripe, as in the case of Dill.

Fennel is largely used for cattle condiments, and Indian or Levant produce will probably be used for these. The usual price for German Fennel is about 35s. per cwt., and an English crop should be grown with good profit at this price. Levant Fennel sells at 25s., and East Indian at 20s. per cwt.

GOLDEN SEAL (*HYDRASTIS CANADENSIS*, L.).

Prospects.—Golden Seal is an American drug, the price of which has risen from 5s. per lb. in 1905 to 20s. or more in September. Such a high price enables cultivation to be practised on a commercial scale both in America and in England, even with the great expense of artificial shading in order to simulate natural conditions. Cultivation of this drug might become a paying proposition to anyone who could solve the problem of the

Golden Seal is propagated by dividing up the rhizomes of old plants in late spring (April or May). These bear prolific lines of dormant buds from end to end of the rhizome, and a living piece containing one of these will grow under suitable conditions. The pieces are planted in rows 6 inches apart with 1 foot between the rows. The plant usually bears a single leaf the first year, and two leaves and a single flower the second year. Golden Seal is a slow but persistent grower under suitable conditions, the time between planting and harvesting being three years. The plants should increase fourfold in two seasons by dividing up the rhizomes. A light mulch of leaves in autumn affords the best protection from frost.

Hydrastis can be grown from fresh seeds, which germinate slowly, but the seedlings do well if they get over the first season in a strong condition. The seeds are sown in fine potting soil and covered lightly. In all transplanting operations the growing beds must not be trodden upon. If artificial shade is necessary, this could be given by slats overhead arranged to turn on edge or lie flat, on the lattice window-blind principle. The initial

difficulty would probably be to obtain a supply of cuttings of the living rhizome.

Yield.—After initial experiments commenced in 1899 on a small plot at Washington, the United States Department of Agriculture gave the production as 5,120 lb. of fresh roots per acre, or 1,500 lb. of marketable roots. In 1912 the Department reported that the cultivation of Golden Seal was "successfully established."

(To be continued.)

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

SOME GOOD MICHAELMAS DAISIES (A. S.).—The undermentioned varieties are among the very best in the sections named, and can be depended upon to produce a splendid display in the autumn: Aster cordifolius section—Aldeboran, Little Boy Blue, Sweet Lavender, Little Bo-Peep, Ideal and White Diana. Aster ericoides section—Perfection, Desire, Hon. Edith Gibbs, Simplicity, Star Shower and Daydream. Aster vimineus section—Freedom, Osprey, Esther, Delight, White Heather and Hon. Vicary Gibbs.

HOW TO HYBRIDISE MICHAELMAS DAISIES (E. H.).—This is very simple, but requires much patience and perseverance to effect any startling novelties, as one must be prepared for a very large majority to be practically worthless. It is contended by many that the various species will not cross. This is not so, as many of the more beautiful varieties now in cultivation have been produced in this way. Immediately the flowers of the varieties it is intended to cross are fully developed, the pollen should be taken from one to the other and some light gauze placed over the flowers to prevent bees interfering with them. The seed should be picked when ripe and sown immediately in light sandy soil, raised in gentle heat, and planted out the following spring.

PLANT FOR WALL GARDEN (F. A. Eyn).—You ask for a plant for this purpose, though the context of your letter rather implies that you are referring to a small "walled-in" garden, which is another matter. For the latter you might plant Spiræas, Liliums candidum, tigrinum, croceum and umbellatum in variety, Phloxes of sorts where the shade is not dense, Solomon's Seal, Foxgloves, Canterbury Bells, Lily of the Valley, Lenten and Christmas Roses, and quite a series of Flag Irises, which alone might with proper treatment prove a signal success. In the shadier parts Ferns, Squills and Primroses would be very charming. If we have wrongly interpreted the meaning of your letter, please write us again. The best time to secure the plumes of Pampas Grass is when they are about three parts matured. Their fleeciness is increased by washing and drying to some extent, though this, together with their form and silveriness, is often much more a question of variety alone. To some extent we believe the plumes are artificially bleached, though we are not acquainted with the exact process.

THE GREENHOUSE.

GRUBS IN BEGONIA TUBER (H. B.).—The larvae are those of the weevil Otiorrhynchus picipes. We recommend you to turn all the plants out of the pots and shake the pest out. It may also be attacking Pelargoniums, Cyclamen and Primulas if you grow them, and these should be attended to in the same way.

ADVICE ON OLEANDERS (E. F. Browne).—One reason why the flowers of the Oleander fail to develop is lack of nourishment at a critical time. They need a liberal quantity of water during the summer months, with frequent applications of weak liquid manure. Another cause that is apt to prevent the flowers opening is that frequently young shoots are pushed out immediately below the head of flower-buds, and if these are not removed they grow away freely at the expense of the buds, which, consequently, make no further headway. You may, if you wish to do so, cut back your plants next March, when, if kept warm and frequently bedewed with the syringe, they will soon start again into growth. As soon as young shoots are pushed forth, the plants may be repotted or given a good top-dressing. Though this treatment would lead to the production of more bushy plants, it is very doubtful if you would get any flowers next season. For the successful cultivation of the Oleander protection from frost is necessary; therefore your plants would not survive the winter outside even if planted in a sheltered spot.

WORKING GREENHOUSE PROFITABLY (P. Tonks).—If you will take advice that is backed by forty years or so of practical nursery training and experience of such questions as that to which your letter refers, it is contained in two words, viz., "Don't dabble." You say you have so many dozens of Carnations and Chrysanthemums, and, of the former, that number of dozens is just that number too many. In other words, you do not want them; they will be in your way. The Chrysanthemums may be all right if the sorts are right, but of that we have no information. If the Tomato is to be your main summer crop, you want that crop early, when prices rule high.

Therefore you require your greenhouse at liberty early, so that there will be no halting between two opinions. In commercial gardening for profit, whether under glass or elsewhere, crops are required to work the one with the other, so that there will be no gaps and no loss of time. You have, as a matter of fact, to keep in mind the well-known adage of "what you lose on the swings you must make up on the roundabouts," and work the crops accordingly. It is, in short, all a question of wheel within wheel, and for the reasons stated Sweet Peas will be in the way of Tomatoes. In so limited a sphere you require a few fixed crops, crops that have definite flowering periods, and which, having finished their function, may be cleared out with impunity. To this end no set of crops would prove so profitable as forced Daffodils and Tulips for the winter, with Tomatoes and Chrysanthemums for succession. The first named would require some outlay and knowledge, and possibly also a little expert professional advice at the outset to put you fairly on your feet. It would, however, be worth doing.

MISCELLANEOUS.

NAMES OF PLANTS.—R. F. C.—Not recognisable in the condition sent; send again next year when developed. —W. Philpotts.—The Strawberry Tree, Arbutus Unedo. Propagated by seeds sown in sand in cold frame in March.

NAMES OF FRUIT.—H. Lester.—Apples: 9, Lord Grosvenor; 10, Mank's Codlin; 15, Striped Beaufin; 19, Kentish Fillbasket; 23, Pickering's Seedling; 24, Nelson's Codlin. Pears: 1, Belle Julie; 3, Durondeau; 4, Doyenné du Comice. —J. P.—1, Glastonbury; 2, Magnate; 3, decayed; 4, Beurré Claircau; 5, Beurré Hardy; 6, Uvedale's St. Germain; 7, Marie Guise; 8, Josephine de Malines; 9, Beurré Sterckman; 10, Durondeau; 11, Beurré Dubuisson; 12, Dana's Hovey. —H. Chapman.—Adam's Pearmain. —East Hants.—1, Bramley's Seedling; 2, American Mother; 3, Hambleton deux Ans.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THE fortnightly meeting held on the 17th inst. was of unusual variety, excellence and interest, the several departments—vegetables, Orchids and flowering plants—being well represented. In the latter the great avenue of Chrysanthemums from Lewisham outclassed everything else, just as did the vegetable collection of Messrs. Sutton at the other extreme in its way. This last, indeed, possessed an importance of its own, at once national and, therefore, far-reaching, as well as of high educational value. It will doubtless remain as an object-lesson for all time. Orchids, if not numerous shown, were full of beauty and variety. Carnations and Violets charmed by their fragrance, and were greatly admired by the large number of visitors. The Orchid committee gave awards of merit to two, and the floral committee to three, novelties.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (Chairman), and Messrs. E. A. Bowles, F. W. Harvey, J. W. Barr, J. Green, W. J. Bear, G. Reuthe, T. Stevenson, C. R. Fielder, C. Blick, J. Hudson, J. F. McLeod, J. Jennings, J. Dickson, A. Turner, J. T. Bennett-Poë, C. E. Pearson, W. P. Thomson, E. H. Jenkins, W. Howe, W. A. Bilney, C. Dixon, W. B. Cranfield and J. W. Moorman.

Messrs. H. B. May and Sons, Edmonton, displayed a table of winter-flowering plants, among which were nice displays of Cyclamen in white, rose and carmine shades, and the newer winter-flowering Begonias. Of these latter, Optima (orange), Mrs. Heal (carmine) and Exquisite were the most important. The Gem (very dwarf, carmine red), Gloire de Lorraine and Glory of Cincinnati (both very charming) were also in this group.

Messrs. Stuart Low and Co., Enfield, also had a charming display of winter-flowering plants, the Begonias bearing that name being prominent. Of these, Exquisite (deep pink and white), Fascination (orange), Mrs. Heal (carmine), Scarlet Beauty, Emita (deep orange) and The Gem were the more important. Cyclamen, Statice profusa and Acacias were also shown. In a separate group a feature was made of winter-flowering Carnations, the huge vases containing such good things as Satin Robe, Philadelphia, Gorgeous, Princess Dagmar (crimson, with fine Clove scent), Mrs. Mackay Edgar (pink), together with Snowstorm and White Perfection (whites).

Messrs. Godfrey and Son, Exmouth, displayed a table of single-flowered Chrysanthemums in variety. Such as Eldorado, Miss Margaret Gildley (bronze), Golden Mensa, Mollie Godfrey (rose amaranth), Audrey (golden), Gold Cup, Cardinal (red) and Market Queen (double, an improved Niveus) were all fine.

Miss Baird, West Malvern, set up a small yet artistically arranged group of Chrysanthemums.

Messrs. Barr and Sons, Covent Garden, W.C., staged a variety of Nerines, also such good hardy flowers as Kniphofia aloides glaucescens, Irises stylosa and alba, Cyclamen neapolitanum, White Hoop-Petticoat Narcissus, Galanthus Elwesii and fine vases of Helleborus altifolius (the latter very fine).

Mr. Charles Blick, Hayes, Kent, showed plants of a capital pink-flowered Perpetual-flowering Carnation named Princess Marie José. It is pleasing in colour and of much refinement.

The Misses Hopkins, Shepperton-on-Thames, had a nice lot of Gentian flowers, together with flowering examples of Hypericum empetrifolium, Primula capitata and Lobelia cardinalis, in a group of hardy alpine flowers.

Mr. G. W. Tyser, Oakfield, Mortimer, had specimen trays of exhibition Chrysanthemums, chiefly of the incurved section. They were a nicely grown lot.

Messrs. Felton and Sons, Harrow Square, exhibited vases of the handsome single-flowered Chrysanthemum Isobel Felton, which is of clear yellow colour. The variety was about six inches across, and of a fine decorative excellence.

Mr. C. Engelmann, Saffron Walden, had a sumptuous lot of Carnations, the vases of Carola, Scarlet Carola, Enchantress Supreme, Fanny (fancy), Champion (scarlet), White Enchantress, White Wonder and Lady Northcliffe being exceptionally fine. Gorgeous was also in good condition.

The Misses Price and Fyfe, Grove Park Nursery, Lee, S.E., displayed some nice vases of Carnations, Mandarin, a yellow-ground fancy, being particularly good. Excellent vases of Chrysanthemums, as Dazzler, Golden King, Snow Queen and R. F. Felton (gold), were very fine.

Messrs. Allwood Brothers, Hayward's Heath, showed splendid vases of Carnations Wivelsfield White, Mary Allwood, Salmon Enchantress, Princess Dagmar (crimson), Philadelphia (pink), Champion (scarlet), Fairmount (heliotrope), Gorgeous, and Bishton Wonder (heliotrope self). Many others were shown in smaller array.

Mr. Clarence Elliott, Stevenage, again showed a quantity of Gentiana acaulis flowers, together with Iris alata and a variety of alpines, of which many were in flower.

Mr. J. Kettle, Corfe Mullen, Dorset, showed Violets in delightful variety. La France, Princess of Wales, Ascania (all of the large-flowered set), Mrs. Arthur, Mrs. Kettle and Mrs. Astor (varying shades of blue in the doubles) were also well represented.

Earl Brownlow, Ashridge, Kent (gardener, Mr. Robertson), sent a display of winter-flowering Begonias, Lady Cooper (deep salmon), Apricot, Clibran's Pink and Scarlet Beauty being the more prominent.

A large group of Chrysanthemums, entirely composed of single-flowered sorts, was staged on the floor opposite the entrance by Messrs. Peed and Sons, West Norwood, S.E. Some of the more distinct were Doreen (golden), Nora Peed (bronze), Phyllis (reddish), Golden Mensa, Stuart Smith (white), Margaret de Quincey (pink), Portia (chestnut red) and Sir Walter Scott (rich yellow).

Mr. L. R. Russell, Richmond, showed a group of berried shrubs, Pernettya, Skimmia, Aucuba, Crataegus and others, in pots, with Cotoneaster, the Strawberry Tree and Hollies.

Messrs. Wills and Segar, South Kensington, had a nice lot of Erica hyemalis rosea and E. nivalis (the latter a mass of pearly bells). Orange trees in fruit were also a feature.

Mr. G. Reuthe, Keston, Kent, had a choice lot of Nerines, of which N. flexuosa alba and N. pudica were very beautiful. Tropaeolum tuberosum was in good condition, also Sternbergia lutea.

Messrs. W. Wells and Co., Limited, Merstham, had Chrysanthemums Merstham Jewel (bronze), Mrs. Loo Thompson (soft yellow), Mary Morris (fine bronze single), W. Rigby (rich yellow) and Queen Mary (both of great size), Commodore (crimson) and Mensa (white).

Messrs. W. Cutbush and Sons, Highgate, N., had choice Carnations in vases, White Swan, Triumph, Sunstar, Lady Ingestre and White Enchantress being the more important.

Messrs. J. Hill and Sons, Barrowfield Nurseries, Edmonton, had a glorious table of Ferns, chiefly in specimen form and admirably grown withal. Among the best was a very fine example of Onychium auratum, of very delicate tracery and beauty. It was, indeed, a charming plant. Polypodium crispum (fine glaucous tone), Davallia tenuifolia Veitchii, Gleichenia semi-vestita, Adiantum scutum, Gleichenia Mendelii, Adiantum trapeziforme, Polypodium irioides ramo-cristatum, Gleichenia longipinnata, Asplenium serra (Brazil) and Davallia ciliata were all imposing specimens and finely grown. Some excellent pieces of Platycerium were also noted in the group, and a nice specimen of the rarely seen Marattia attenuata.

Messrs. H. J. Jones, Limited, Lewisham, S.E., were awarded a gold medal for what in effect was a great avenue of Chrysanthemums, brought into being by table displays arranged at right and left of a spacious gangway. Through this it was possible to promenade and view the flowers at will, and certainly nothing finer of its kind has ever been displayed. Following their well-known style, tall vases and stands 4 feet or so high were employed in the background, each containing a score or so of handsome flowers. In this way some five hundred giant flowers of exhibition standard were utilised, to say nothing of front vases containing single and decorative sorts galore. We have not space to do justice to such an imposing array of the "Queen of Autumn Flowers," and give a few of the best. C. H. Curtis, yellow incurved, appealed by reason of refinement and colour. Bob Pulling is a glorious yellow. Mrs. R. C. Pulling is a yellow Japanese and very large. Lady Grace is white and mauve. Sir William Dunn (crimson) has a gold reverse. Mrs. Bai is a lovely pink Japanese. Mrs. H. Eland (mauve), Miss Archer and Junon (pink) are a trio of Anemone-flowered sorts: while Audrey (yellow), Jessica (golden amber), Buttercup (golden yellow), Excelsior (golden amber) and Arthur Harvey (deep rose pink) are a set of singles calculated, we think, to satisfy everybody.

Mr. Amos Perry, Enfield, again showed hardy Ferns, the group on this occasion being of Polystichums and Scolopendriums, the latter in many of the finest tasselled varieties. All were varieties of S. vulgare, and included grande, latifolium, cristatum, digitatum, grandiceps, with all the more distinct and ornamental of the ramo-cristatum forms and others akin. We welcome these plants for their evergreen qualities as much as for their fine ornament.

THE GARDEN.

No. 2246.—VOL. LXXVIII.

DECEMBER 5, 1914.

NOTES OF THE WEEK.

Honour for a Colchester Firm.—Messrs. R. Wallace and Co. of Kilnfield Gardens, Colchester, have just received the Royal Warrant appointing them Nurserymen and Purveyors of Hardy Alpine and Aquatic Plants to Her Majesty Queen Alexandra.

The Victoria Medal of Honour in Horticulture. It is with pleasure that we learn the Royal Horticultural Society has conferred the Victoria Medal of Honour, instituted to commemorate the glorious reign of Queen Victoria, on the following: Captain W. Stackhouse C. Pinwill, a Cornish amateur who has all his life collected rare plants and has been most liberal in distributing them gratuitously far and near; Mr. Joseph Cheal of Crawley; Mr. Whytock, gardener to the Duke of Buccleuch, Dalkeith; and Mr. William Cuthbertson of Messrs. Dobbie and Co. of Edinburgh.

Mossy Saxifrages in Winter.—Now that the flowers of most of our rock garden plants have departed, the value of those possessing beautiful foliage is fully appreciated. On looking through the rock garden a few days ago we were very pleased with the beautiful green carpets of Mossy Saxifrages, the fresh, verdant tint making a charming contrast to the grey sandstone. *Saxifraga hypnoides* and *S. muscoides*, with several of their varieties, were particularly effective.

Wallflowers in December.—For some time now we have been cutting some fine spikes of Early Paris and Yellow Phoenix Wallflowers. The seeds were sown in April, the seedlings pricked out when large enough, and given no more attention until we started cutting the flowers, which we hope to continue to do for some time yet, or even the winter through, providing the weather is not too severe. At such times this favourite flower is very much appreciated, and we would advise our readers another season to grow some of these varieties.

A Late-Flowering Torch Lily.—During the past few weeks one of the most attractive features in the outdoor garden at Kew has been a large bed of Torch Lilies situated near the Orchid Houses that form part of the famous T range. The variety is *Kniphofia aloides maxima*, and even at the end of November, in spite of several severe frosts experienced a week

or ten days earlier, the handsome red and yellow flower-spikes were in splendid condition. In common with other Torch Lilies, this variety needs light, sandy soil that has been heavily manured.

The Royal Horticultural Society's Lawrence Medal.—We understand that the Lawrence medal, awarded each year by the Royal Horticultural Society for the best gold medal group staged at any of the society's shows during the year, has been awarded to Sir Everard Hambro, K.C.V.O., Hayes Place, Kent (gardener, Mr. Cranfield), for his magnificent group of alpine in pots. All those who have had the pleasure of seeing the alpine from Hayes Place will, we think, agree that this signal honour is fully deserved.

on September 24, and is now a prisoner in Germany. To fill the places of those growers who are fighting, their parents, wives and children have come forward, and are working bravely and without complaint to keep things going. Paris is now wearing a more cheerful aspect. A great many foreigners who left the city during the dark days of August have now returned, and these help to keep business going. We are sure that all our readers will join with us in the earnest wish that fair France and gallant Belgium will soon be cleared of our enemy, and that substantial reparation will be made to them for the damage and misery caused.

Pear Louise Bonne of Jersey.—It is doubtful whether there is a more reliable Pear of really good quality for small or large gardens than the one illustrated on this page. It is an old variety, having been raised in France as long ago as 1780. The fruits, which are in season during October, are of medium size, yellowish green, with a dull red flush on the exposed side. The flesh is white, very juicy and of good flavour. So far as our experience goes, this Pear always crops well, no matter in what form it is grown. We have it in espalier and cordon form, and can always rely on the trees to produce fruits, even when most others fail. Now that fruit trees are being planted, a few at least of this Pear should be included. Quite small trees budded or grafted on the Quince stock will bear fruit.

FRUITS OF PEAR LOUISE BONNE OF JERSEY, AN EXCELLENT OCTOBER VARIETY. TREES SHOULD BE PLANTED NOW.

Paris in War Time.—From a letter received on Saturday last from Comte d'Estienne of Messrs. Vilmorin, Andrieux et Cie we are able to gain some idea of the difficulties under which horticultural business is being conducted in Paris at the present time. Of Messrs. Vilmorin's staff, over 400 out of 700 members had to join the Colours of our Allies as soon as war broke out, and since then many others have also been called up. So far six members of the staff have been killed, twenty wounded and several are missing. Five members of the family, and bearing the name of Vilmorin, are with the French army, and one of them, M. Jean Vilmorin, Lieutenant au 9ème Cuirassiers, was wounded at Peronne

as long ago as 1864, it is seldom that we find it in gardens. It is difficult to understand why, as at the end of November some plants that we have in a sunny border under the dwelling-house were still in full flower. The blossoms are deep red, and remind us somewhat of *Ixias*. When grown outdoors it needs a warm, sunny position and rather light, well-drained but rich soil. In colder districts it needs pot cultivation, with the pots plunged to their rims in ashes in a cold frame throughout late spring, summer and autumn, these being taken to the greenhouse or conservatory to flower during October and November. It is known botanically as *Schizostylis coccinea*, and is easily propagated by division in the spring

The Kaffir Lily.—Although this beautiful little South African plant was sent to this country

CORRESPONDENCE.

(1 Editor is not responsible for the opinions expressed by correspondents.)

Quince Jelly.—The thanks of your readers are due to Mr. E. Molyneux for giving, in your issue for November 7, page 540, the recipe for Quince jelly. Following faithfully the directions there given, we have been successful in making a good quantity of this jelly, which I have no hesitation in saying is the best preserve I have ever tasted, a statement that is endorsed by numerous friends who have tried it. This jelly is bright red and very attractive, and the flavour is quite unique. Thanks to Mr. Molyneux, we now have a use for fruits that in the past have been regarded as of little value.—NEMO.

Autumn - Fruiting Straw-

berries.—Seeing how prolific the large alpine Strawberry is and the length of time it continues to fruit, it is surely wonderful that people so seldom grow it. Here in mid-Oxfordshire we were during the second week in November having dishes of the fruit for dessert, and the fruits nearly all average an inch in length by $1\frac{1}{2}$ inches in circumference. We have never been without a supply of them since June, when, besides those used in the house, we made jam from them. The plants are in a narrow border under a west wall, and as the birds never seem to touch the fruits, they do not require netting.—A. LA T.

Parochetus communis

Flowering Late.—For some reason or other this delightful trailing plant did not flower with us until mid-October, though it ought to have done so in July. Though seldom referred to, it is, nevertheless, strikingly pretty with its clear pale blue flowers, which arise out of the axils of the Shamrock-like leaves. It makes a good rockery plant, but should not be planted where it is hot and dry. Some authorities say it is not absolutely hardy in cold districts, so slight protection should be given; or portions of the plant can be potted up and kept in the cold frame in the winter—an easy matter, seeing it roots at intervals along its stems.—C. T., *Highgate*.

Salvia Fireball.—In your issue of November 14, page 552, I noted a well-merited tribute to this plant. We usually fill a large bed in front of the house with it here, and many passers-by stop to admire it. Such a brilliant bit of colour does it make in the landscape that when travelling on the railway, which runs at a distance of nearly half a mile in front of the house, I have heard folks in the train call one another's attention to the bed. Your correspondent speaks of making a comparison between plants raised from cuttings and those raised from seed. We have tried both

plans here, and, unless I am a false prophet, he will find the comparison—as is indeed the case with most flowering plants—to result immeasurably in favour of seed.—F. HERBERT CHAPMAN, *Rye*.

Pruning Cordon Fruit Trees.—At this busy season one has not much time to indulge in writing, but I cannot let the otherwise excellent article by "A. B. Essex," in your issue for November 28, pass without a remark upon one sentence contained therein: it is, "In the winter these side shoots or stumps are cut to within two buds of their bases. . . . This is the way fruit spurs are made." Forty years' experience in pruning fruit trees leads me to say that, so far from the above being a fact, it is just the way fruit spurs are *not* made, and such close pruning has been the cause of more failures in fruit-growing than

growth will your tree be. In the case of pyramids, in which each branch is (or should be) treated as a cordon, trees hard pruned like this become dense thickets, splendid places for blackbirds to build in, but of little other value. And what thousands there are in this country! Nearly every garden one goes into contains examples, and doubtless this is why a school of advisers has arisen which says, "Don't prune at all; let your trees grow naturally." The general reply to my advice is that spurs thus left are unsightly and the spurs get too far away from the main stem. True; but the time to reduce them is after the lower buds have become fruit buds. These fat fruit buds are easily recognised by any amateur, and when once well developed, any growth beyond may be cut off, as each bud has its own leaves as well as bloom, and needs nothing to draw up sap. I am, of

course, speaking of Pears and Apples. In this way the fruit is kept near the stem, and the trees are not crowded with wood. One word in conclusion: If your trees are vigorous, go one better than the advice given above—pinch to six leaves instead of five, and prune to five buds instead of four.—A. H. PEARSON, *Lowdham, Notts*.

A November - Flowering Plantain Lily.—Flowering during October and November, the Plantain Lily named *Funkia tardiflora* is one of the most valuable plants of the family. The *Funkias* are, as a whole, more or less partial to a little shade and moisture. For the subject of this note, as it blossoms during November, shelter is very desirable, as, though perfectly hardy plants, several degrees of frost, which is naturally more severe in the open, soon spoils the flowers. A western aspect is desirable, to avoid the morning sun reaching the flowers when there is a little frost. A sheltered nook in the rock garden, in the hardy fernery, along the front of the shrubbery border, or planted beneath a bed of deciduous shrubs are all good. At Kew one of the best effects and most successful plantings is

FUNKIA TARDIFLORA, A PLANTAIN LILY THAT FLOWERS OUTDOORS DURING NOVEMBER.

anything else I know of. Bear in mind that this treatment is recommended for young and vigorous trees which are in the course of being formed. For "summer pruning" I should read "summer pinching." Pinch the young side shoots back to five leaves instead of four, while the shoots are young enough to do this easily with the thumb and finger nails; this prevents their getting too strong. Subsequent growths pinch back to two or three leaves beyond the first pinching, and in the autumn prune back to four buds. If this is done, the following season the two upper buds will produce growth, the two lower buds will form bloom bud, and this is how fruit spurs are made. If you prune young trees to two buds, they will both make wood growth, and the more this treatment is carried on, the more densely crowded with

in the Bamboo Garden. This *Funkia*, in common with other members of the family, thrives freely in a rich loamy soil. Increase is readily effected by division of the clumps in March, which is also the best time for replanting. When first introduced it was named *F. lancifolia* var. *tardiflora*, but the plant is now more generally regarded as a distinct species. It has shining dark green leaves 5 inches to 6 inches long, $2\frac{1}{2}$ inches to 3 inches broad in the centre, tapering at both ends. The flowers are a delicate light purple, freely produced on a raceme 8 inches to 12 inches in length, sometimes more, the flowers closely arranged towards the top, thirty to forty or more in a dense raceme. *F. tardiflora* was first introduced to this country in 1895, in which year plants were obtained for Kew from Herr Max Leichtlin.—H. O.

Pear Charles Ernest.—I was interested in your reference to this Pear and the beautiful illustration of a tree in full fruiting condition on page 566, issue November 21. The Pear is all that is claimed for it, and should be largely grown by amateur cultivators. I am growing the tree as a cordon, but intend to let it develop a little beyond the true cordon stage, as it is growing in the open border and not against a wall. Numbers of trees can be grown in a small space if so treated. The foliage of this variety is the most distinct of any that I have seen, being so very glossy, and the fruits, too, are smooth-skinned and shiny.—GEORGE GARNER.

Late-Flowering Rockery Plants.—We had well into November five rockery subjects in particular carrying a sprinkling of flowers, and even now (November 19) there are a few open flowers on some of them. Indeed, one family—the *Oxalis*, species *rosea*—is still covered with buds, which are no longer able to open fully, even when the sun shines on them, owing, of course, to lack of warmth and its short stay. The other subjects are *Erodium cicutarium*, *Chrysogonum virginianum*, *Erigeron mucronatus* and *Wahlenbergia gentianoides*. Of these last four I do not know to which the "palm" should be given for persistent flowering.—C. T., *Ken View Garden, Highgate*.

Autumn Scenes in Cumberland.—When I was recently paying a visit of nearly a week to the beautiful region of Borrowdale in Cumberland, above Derwentwater Lake, nothing was more exquisite in the valleys and glens than the wild Rose trees, covered with their luxurious coral berries, hanging picturesquely in the waysides over the river Derwent on my way from Lodore to the hamlet of Roswath at the foot of Scawfell. The autumnal tints were still marvellously effective on the mountain slopes. Beneath them, in the near distance, gleamed the waters of the silvery lake. Above, on Bowfell, Scawfell, Skiddaw and Silver Craig, glittered through the pure, serenely silent atmosphere great diadems of snow. On the garden walls of many of the cottages in Borrowdale that venerable, fragrant and richly effective Rose *Gloire de Dijon* was still in wondrous bloom. The lovely *Snowberry* was very conspicuous everywhere around The Grange and Lodore, and to me it seemed to attain in those regions an unusual size.—DAVID R. WILLIAMSON.

When to Propagate Carnations.—I am far from doubting Mr. Weston's contention that trade growers find January and February the best time to propagate Perpetual-flowering Carnations. I have read all the books which have appeared on the cultivation of this flower, and know that Mr. Weston is right in saying so. At the same time, gardeners find it better to propagate in advance of the trade grower. Two gardeners have already written to THE GARDEN agreeing with me on this point, and I know several who used to propagate after the New Year who have adopted autumn propagation. I met the owner of a ducal garden at a railway junction not long ago, and while waiting for a train I was told that the gardener, who up to the previous year had struck cuttings late, had for this year also adopted autumn striking. Flowers had not been so abundant as was hoped for; hence the change. This year, owing to the war, our arrangements have got out of joint, and the cuttings could not be got in till much later; and I have no doubt the results will be on the whole less satisfactory than hitherto.—K. P. BROTHERTON.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

THE colours of the flowers have never been richer, nor the latter more refined in every way, than they have this year. I am not solely referring to the large flowers grown specially for exhibition, but to those also for grouping at home and for the supply of cut flowers to place in vases. Although the weather has been damp, foggy and dull, with occasional spells of hot sunshine, there have not been such bad cases of damping of flowers as in some past years. Many of the new varieties possess petals with glossy surfaces, and such resist damp more than those with dull, or what may be termed rough, surfaces. The value of

Late-Flowering Varieties is very great, and amateur cultivators would be acting wisely if they grew more of them in future years and placed their orders for cuttings for next year's plants as soon as possible. Some cultivators have a mistaken idea that the plants may be propagated late in spring, and so secure late flowers of the best quality. Smaller plants bearing nice flowers may be so grown if the shoots are not stopped too late in the summer; but the finest specimens are grown when the cuttings are propagated early. All sucker shoots now appearing on such varieties as *Embleme Poitevine* (yellow), *A. J. Balfour* (pink), *Baldock's Crimson* (scarlet red), *Mme. R. Oberthur* (white), *Nagoya* (deep golden yellow) and *Tuxedo* (orange bronze) should be retained and inserted as cuttings before they get too much drawn up. Thus, a nice batch of young plants will be available instead of spoiled shoots in January.

Composts for Cuttings.—Composts for cuttings of all varieties should be very carefully prepared. The soil so used remains around the roots throughout the season, and it must not only be of a character to induce the free formation of roots, but act as a storehouse for foods given later on. Quite fibreless soils are unsuitable. I like to sift out the fine soil and replace it with good, sweet leaf-soil, retaining the most fibrous portion of the loam only; then add sufficient washed and dried coarse sand to make all porous. Manure at this stage is not needed. The turf should be selected now; it must be that in which all grasses and their roots have perished. Older turf than this should not be used if it can be avoided.

Chrysanthemum Roots.—Directly the flowers have faded or been cut, the stems must be cut down to within a few inches of the soil; quite low down if suckers are plentiful. Then place the pots in an open position in a greenhouse or frame, so that air and the maximum amount of light will reach them. If cuttings are plentiful and in a number of pots, discard some pots to make room for others, and thin out the weaker of the remaining cuttings. This means sturdiness. Where cuttings are scarce, remove a little of the surface soil and replace it with a sandy mixture, place the pots in a warmer house and keep the soil moist. In nearly every case cuttings are induced to grow. With the Editor's permission, in an early issue I will give a list of new varieties suitable for amateurs to grow for exhibition and home use.

AVON.

POTASH MANURES.

HOW TO SUPPLEMENT SUPPLIES.

AT one time, not many years ago, gardeners relied almost entirely upon natural manures to maintain the fertility of their gardens; but with the advent of the motor the horse is fast disappearing, and natural manures are in some districts practically unobtainable. In consequence of this shortage chemical manures are being used more and more extensively year by year. Ready-made fertilisers are supplied by the trade, but some of these are very expensive, and where the gardener has to study economy he prefers to buy the ingredients and make his own mixtures.

No fertiliser is complete without potash, and we have been accustomed to rely upon kainit and sulphate of potash for this. Both of these salts have been obtained from Germany. The German potash deposits near Strassfurt yield a vast supply of kainit, from which sulphate of potash is obtained. Practically all the potash in use for manurial purposes comes from Germany. The writer is not in possession of the latest figures as to the annual yield of these German mines, but in the year 1900 1,158,000 tons of potash salts were used for agricultural and horticultural purposes. It will be seen, therefore, that as we rely almost entirely upon Germany for our potash supply, we are faced with the prospect of a potash famine for this year.

There is, however, one source of supply open to many gardeners, and that is by the careful use of wood-ashes. In the *Journal of the Board of Agriculture* for November, Dr. E. J. Russell contributes a very useful and timely article on wood-ashes as a source of potash. Experiments have been carried out at Rothamsted, and wood-ashes have been proved to be almost equal to kainit. Dr. Russell points out, however, that wood-ashes should not be exposed to rain before digging into the ground. Two samples were analysed both before and after exposure to a slight shower, with the following result:

Percentage of Potash.			
	Sample A.	Sample B.	Mean of A to B.
Ash collected dry	10.7	9.6	10.1
Ash collected after rainy night	5.7	4.4	5.0

It will thus be seen that although only 0.09 inch of rain fell during the night, half the potash was washed out of the ash.

All hedge trimmings and tree prunings should be burned, and the ashes collected as soon as cold and kept in a dry place till they can be used. The early spring, just before sowing, would probably be the best time to apply the ashes, which should be used at the rate of 8lb. to 16lb. per square rod.

A. E. B.

LILY OF THE VALLEY.

RETARDED crowns of Lily of the Valley may be had in flower by the end of the year, providing they are potted and placed in the forcing-pit at once. Only moderate heat should be applied at first, but this may be increased as growth develops, and when the flowers are fully expanded, the plants ought to be removed to a cooler temperature in order to prepare them for house decoration. Neither the roots nor the atmosphere should be permitted to become dry during the forcing period. J. D.

HARDY AZALEAS FOR PRESENT PLANTING.

THE gorgeous colours assumed by the leaves of many of the hardy Azaleas previous to falling call our attention to a group of plants which delighted us earlier in the year by their showy flowers. The genus *Azalea* is not recognised by botanists; it is now placed in the large genus *Rhododendron*. Garden enthusiasts, however, prefer to reserve the name of *Rhododendron* for the evergreen species, and retain *Azalea* for the deciduous kinds. The name signifies very little, and does not affect the usefulness of the shrubs. Azaleas are useful for many purposes; they are equally delightful when planted in beds on a lawn, as at Kew, with all sorts of shades of colour intermixed in dazzling bewilderment, yet no two shades clashing; planted in groups in shrubberies, as is often apparent in our parks; or grouped by the acre in a semi-wild state in thin woodland, as is practised by Sir Edmund Loder at Leonardslee and by other owners of large estates.

Providing the soil is right, Azaleas give little uneasiness regarding culture, but they detest lime or a sour condition of the ground. Peaty, loamy or sandy soil, providing lime is not present, suits them admirably. The only pruning that is required is the removal of the flower-heads as soon as the flowers fade, so that the strength which would have been expended on seed production may go to the building up of the young shoots for next year's flowers.

Though the Azaleas usually grown are the hybrids and garden varieties of a few American and one Japanese species, there are other kinds less frequently met with that are well worth attention, and one of the prettiest is the delightful species *Vaseyii*, a shrub which has been introduced from the mountainous regions of Carolina. The flowers are white, slightly flushed with pink, though there are forms with pink and white flowers. Two rare purple-flowered species are found in the Japanese rhombicum and dilatatum, both of which blossom early in May. The purple-flowered *Rhododendron Rhodora* may be classed with the *Azalea* group—it is exceedingly floriferous and showy; while a quaint Japanese shrub with tiny leaves and rosy purple flowers is found in *R. serpyllifolium*. *R. Schlippenbachii* is a handsome-flowered plant from Manchuria and Japan, but, unfortunately, like other Manchurian shrubs, it commences to grow very early in spring, therefore it frequently falls a victim to late spring frosts; hence its suitability for the milder parts of the country only. The hardier forms of the Indian *Azalea*, particularly those of the *amœnum* class, are very suitable for gardens in the South of England and Ireland, while the variety *Kämpferi*, which is found in the mountainous regions of Japan, is equally desirable and showy.

Turning to the kinds which are more frequently met with, we find that the chief species represented are *arborescens*, *calendulaceum*, *nudiflorum*, *occidentale* and *viscosum* from North America, *sinense*

from China and Japan, and *flavum* from the Caucasus. Of this number *sinense* is most easily obtainable in the typical state, for the others have been crossed so frequently that hybrids are far more common than the types. *Rhododendron sinense* is well known to many people as *Azalea mollis*, and during early spring it is a familiar plant in almost every garden and market, for it is one of the most extensively cultivated of all shrubs for forcing, while its rich-coloured flowers make it a popular subject for room decoration. Grown out of doors it comes into flower rather earlier than the American kinds, and is often in full flower early in May. This sometimes leads to

varieties with large flowers have been raised. Under the name of *Azalea rustica* a number of varieties with double flowers have appeared, of which are showy. Named varieties innumerable may be obtained, which collectively are spoken of as Ghent Azaleas, from the fact that Ghent is a great centre of *Azalea* culture and a great many kinds have been raised there. Ghent or American Azaleas are extremely popular, and are adapted for growing in large beds in the open. If an upright growth is being made, it is advisable to shorten the leading shoots; this will induce the plants to break from the base and so form well-branched and dwarf specimens.

Those who know the Azaleas only from their flowers would do well to pay a visit to some large collection during September or early October, when the leaves show almost as great a variety of colour as the flowers do earlier in the year. At such a time one is apt to say that the Azaleas are worth growing for the sake of their autumn colour alone. D.

THE INCENSE CEDAR.

As an isolated specimen on a lawn there are few more imposing trees than the Incense Cedar, *Libocedrus decurrens*, especially when well grown. Unfortunately, many of the specimens that are to be found in this country are by no means good, the branches being gappy and placed at irregular distances on the trunk. Where, however, the soil is good and rich and, though well drained, fairly retentive of moisture, there is no reason why this handsome tree should not be planted and induced to develop its natural character. Botanically the family is closely related to *Thuja*, and in gardens the species under notice is often known as *Thuja gigantea*. The popular name of Incense Cedar is derived from the incense-like fragrance that is emitted from the wood. The tree illustrated is growing on the lawn in front of Frogmore House at Windsor, and is one of the finest of its kind in this country.

FRUIT NOTES.

Pruning Apples and Pears.—Those who plant fruit trees must not think that the work in connection with them commences and ends with the mere act of placing the roots carefully into the soil; as a matter of fact, the really intelligent operations are then about to start, and it is entirely upon the manner in

A FINE SPECIMEN OF THE INCENSE CEDAR
(LIBOCEDRUS DECURRENS) AT WINDSOR.

its undoing, for a late frost may injure its flowers. The blossoms are various shades of yellow, orange and red. It has been crossed with American kinds with good results. The flowers of this species have not the delicious fragrance of the American kinds. The flowers of *R. viscosum* are extremely sticky and powerfully fragrant. From this reason and the fact of its growing in swampy ground it has acquired the name of Swamp Honeysuckle. The Caucasian species, *R. flavum*, is a yellow-flowered kind which bears strongly scented flowers in May. The blossoms are yellow and larger than those of the American species. Crossed with *calendulaceum*, some fine orange-coloured

which they are carried out that success depends. At the outset, trees that come from the many reputable nurserymen of the country are practically certain to be in excellent condition; the earlier steps of cutting to form a satisfactory foundation will have been taken, and it remains with the purchaser to maintain them in a perfect state. There are many little things that will demand attention from time to time; but the operation of pruning, which has to be done each season, is of outstanding importance, and it is impossible for too much thought and care to be devoted to it.

The Best Time.—It is immaterial what form of Apple or Pear tree may be demanding attention, but there can be no doubt as to the desirability of completing all the cutting before Christmas. One would not go so far as to assert that the work may not be successfully done long after Christmas, but one may safely say that we get the worst of the winter weather in the first and second months of the year, and pruning trees is essentially not one of those tasks that one cares to do when the rain is coming down in torrents or there are 10° to 20° of frost. Indeed, to cut during frosty weather, whenever it may happen to come, is an error, since the frost may, and probably will, get into the heart of the shoot, and it is certain that trouble will follow in a very short period. Apart from all this, the cutting that is carried out in November and December is done when the habits of the different trees are fresh in the mind of the worker, and the natural consequence is that the operation will be far better finished off.

The Object of Pruning.—The primary object in view in the cutting of fruit trees is to increase their fertility, and one of the surest aids to this is to permit the free admission of light to all the buds in the centre as well as on the outer growths. To this end the middle of the tree ought always to be kept open, and whenever it is necessary to reduce a shoot in length, the cut should invariably be to an outer wood-bud—that is to say, to a flat, pointed bud on the outer side of the stem—since the new shoot will grow in the direction in which the bud points. Thus, if we cut to a bud on the inner side of the stem, the resultant shoot will grow inwards and tend to fill up instead of keep open the middle of the tree. Much, of course, depends upon individual circumstances, but, generally speaking, all the principal shoots should stand 18 inches asunder, so as to allow of the perfect development of the leaves, without which it is impossible to secure the finest crops of fruit. Where the growths are crowded, they should not always be cut back a portion of their length; on the contrary, it is usually far better practice to cut them clean out from the point of origination. As a rule, the bulk of the crop will be carried on spurs on the old wood, and the pruner should cut hard back to these in the winter pruning. The summer cutting or pinching makes this operation easier; but whether recourse is had to this system or not, the winter cutting must be close back, or the spurs will extend to such a degree that the results will never be satisfactory. It is, of course, always desirable to allow some extension of new wood, and the amount must necessarily depend upon circumstances. When the tree is being formed we have to cut back the new shoots by one-half or two-thirds of their entire length, but after the foundation is perfectly established the actual length will depend upon the available space and the condition of the tree. In any case, all unripe portions, as judged by the colour of the bark, must be removed, and there will then remain anything from 3 inches to 12 inches of new wood,

according to convenience. In all cases it is essential that the natural habit of the variety shall be considered, as, though the principles are the same, there are deviations from them, and it is those who study the different varieties under their charge who achieve the greatest success in the culture of these valuable hardy fruits.

FRUIT-GROWER.

WINTER SPRAYING OF FRUIT TREES.

Now that all the buds of fruit trees are dormant, the spraying with caustic alkali wash, so frequently recommended, can be successfully carried out. Many fruit-growers prefer to wait until early February, just before the buds begin to burst, but that is a busy season in private gardens, and if the spraying is delayed until then it often means

ROSES IN YORKSHIRE.

THERE is abundant evidence to prove that the cultivation of Roses is becoming increasingly popular with the amateur gardener. Whether a man is able to grow a modest twenty representative trees or is able to launch out into beds of individual varieties and colour schemes involving hundreds of plants, there is a fascination and an incentive to go one better that is peculiar to the Queen of Flowers. Sweet Peas, Carnations and other flowers all have their keen adherents, but there is a sort of freemasonry existing among the thousands of amateur Rose-growers that continually provides interest and pleasure.

Coming from Kent into Yorkshire eight years ago, I was told promptly, though kindly, that

A VIEW IN THE AZALEA GARDEN AT KEW. NOW IS THE TIME TO PLANT THESE SHRUBS.

that it is left undone. In response to a number of enquiries that have reached us during the last few days, we give below the particulars of this wash, which is certainly most effective in cleansing trees of moss, lichens and other extraneous growths, which if left not only prove unsightly, but provide excellent cover for harmful insects. The wash is made as follows: Dissolve 2lb. of caustic soda (98 per cent.) in a gallon of warm soft water, then add to it 1lb. of soft soap or treacle, and after the whole is thoroughly dissolved and mixed, make up to ten gallons with, preferably, soft water.

Owing to its caustic nature, this wash is likely to cause injury to the hands of the user, who should wear some old gloves and also old clothes while spraying the trees. A fine spray, so as to thoroughly wet every portion of the stem and branches, is necessary, and a day when there is little or no wind should be selected for the operation.

It was waste of time to plant Roses which did "only moderately well" at the very best. It has been my pleasure to prove by my own experience since then that it is possible to have quantities of lovely blooms from the end of June until the end of October, and this year as well as last until November has passed. On November 14 I cut good blooms of Lyon, Betty and Richmond. On November 15 we awoke to find a level 4 inches of snow, together with frost, which, I fear, has finished the chances of some forty or fifty fine buds remaining on the trees, that looked as if two or three days of mild weather would open them.

The Best Varieties.—For this district it is obvious that great attention must be paid to the selection of varieties. Unfortunately, it is only by a slow and costly experience that many of us are willing to learn the lessons of horticulture. My imagination pictured a line of standards with large heads filled with bloom, giving the

to the entire garden; but a few severe lessons have taught me to pass on to that section of Rose catalogues devoted to dwarfs and climbers. My garden is situated in the northern suburb of Leeds, some three miles from the city, and a more exposed situation can hardly exist. Short of rooming in the entire garden, it is impossible to do more than check the strong winds from north-east, north-west and, last but not least, south-west. Therefore it is not unreasonable to suppose that varieties that do well with me could not fail to be a success elsewhere. In selecting Roses for this district, there is a broad general rule (which, however, has its notable exceptions). The two types of Roses that have given me the best results are, first, the class that is composed of comparatively few petals and is of a rather loose character in the bloom, as, for instance, Edu Meyer or Betty; and, secondly, the Pernetiana type, as represented by Lyon, Willowmere and others. While these are generalities that admit of some latitude, they should by no means be forgotten by the man who is making up his annual list.

VIGOROUS RED ROSES.

One of the Roses that should be in every first dozen is

Gruss an Teplitz, a brilliant crimson that blooms continuously in clusters, having dark foliage and extra strong growth. In one season it will go up to 7 feet or 8 feet, and this is by no means the record in height. To get the best results it should be pruned sparingly. Although so free, it is at the same time decorative. It looks nice pegged down, but I prefer to grow it as a background, against which some of the more refined varieties appear to advantage.

Lieutenant Chaire (H.T.).—Colour, rich velvety crimson. This has done particularly well with me. It produces large blooms—with deep petals and fine cupped form—in abundance, coupled with a sturdy growth. I have no Rose that holds its head up better, and it seems able to resist wind and wet above the average.

Hugh Dickson (H.P.).—Colour, intense brilliant crimson. This cannot be omitted, because of its reliability. It appears to succeed best when allowed to climb, and its colour and fragrance have earned for it a wide popularity. Under this heading must also be included

J. B. Clark (H.T.).—Colour, scarlet, shaded blackish crimson. A most vigorous grower, producing abundance of bloom. This and Hugh Dickson used against a trellised fence or pergola, alternated with Dorothy Perkins, makes a pleasing and effective combination.

Richmond (H.T.).—Colour, bright scarlet. It is very free, and with me a better grower than Liberty. It is a charming button-hole Rose. I have just planted Dora Van Tets, which is claimed

to supersede Richmond, but I have not seen it in bloom in this district.

Gloire de Chedane Guinoisseau (H.P.).—Colour, brilliant red, and the recognised counterpart of Frau Karl Druschki, but exquisitely perfumed. I wish it were not such a shy bloomer, as the few flowers that have appeared have been of perfect form and colour. It is undoubtedly an exhibitor's Rose.

Roundhay.

E. WATERS.

(To be continued.)

THE BANKSIAN ROSES.

HOW TO MAKE THEM FLOWER.

To the enthusiastic amateur cultivator of Roses there is a good deal of fascination about the white

plants which have flowered well have been those growing in gardens where they received practically no attention beyond an occasional thinning out of some old wood or the curtailment of too venturesome shoots. The soil in which these successful Banksians are growing varies considerably, ranging from fairly stiff clay to almost gravel. The aspect has either been south, south-west or west. Can the secret of success be in letting the plants well alone, or is it more to do with aspect? As THE GARDEN has always taken a foremost place in the advancement of the Rose, it would be interesting and exceedingly useful if other readers would send the Editor their experiences with these fascinating but, alas! to many, elusive Roses. By so doing, they will render many fellow amateur, and possibly some professional, rosarians valuable assistance.

A. B. ESSEX.

ROSE-GROWING IN TOWN GARDENS.

THOSE who are planting new beds with Roses should have the positions prepared as long as possible in advance, for the soil will have

been raised considerably in trenching, and a month is not too much time to allow for it to settle again. Where a bed has had to be hurriedly prepared, it may be made firm by treading, but this is only safe when the soil is moderately dry. Trees that have been put into unsettled soil are liable to be "hung"—that is, subsidence takes place beneath them, leaving them suspended over a hollow by their roots—and if this is not immediately corrected, harm will result. For this reason it is advisable to go over all new beds within a week or two after planting, and carefully tread down the soil, making sure that each tree is firmly planted. When fresh plants are added to existing beds to replace others that have failed, the soil should be taken out all round as far as possible without disturbing the roots of the Roses adjoining. The hole made should be about one foot in depth, and this should be half filled with

BANKSIAN ROSES SURROUNDING A DWELLING-HOUSE WINDOW. MANY AMATEURS EXPERIENCE DIFFICULTY IN GROWING THESE.

and yellow Banksian Roses, those green, glossy-leaved ramblers that, even though they may be induced to grow luxuriantly, refuse in many instances to produce their flowers. The reason for this has been attributed to numerous causes, such as unsuitable positions, incorrect pruning and bad soil; but a careful consideration of the circumstances surrounding a number of plants that have come under my immediate notice will hardly place the whole blame on any of these. For some years past I have been acquainted with a number of white and yellow Banksian Roses, some of which flower profusely every year, and others refuse to produce more than an occasional truss or two of blooms. Invariably I have found that the

well-rotted manure and soil in equal proportions, well mixed, with a sprinkling of bone-meal. This should be covered with 2 inches of fine soil, and the whole made quite firm before proceeding to plant the new tree.

In forming pergolas or putting up arches, a little extra trouble at first will save a great deal later on. The wood used should be stripped of bark and made rot-proof by painting with carbolineum or some other protective substance. Oak is best for the purpose, and is so much more lasting than other woods that the extra cost is more than justified. Larch and Sweet Chestnut will, however, take a long time to decay if carefully treated, but Birch and other soft woods rot very quickly.

The parts of the poles which will decay first will be those at the earth level, so that an extra coating of the preparation should be given there. The supports thus treated should be exposed to the air at least a month before being used, or, if put into the ground, defer planting for that amount of time. Those who wish to make their pergolas as permanent as possible should set each pillar in a small bed or collar of concrete built up a few inches above the level of the bed. P. L. GODDARD.

SOME INTERESTING GREENHOUSE PLANTS.

COMMONLY known as Carrion Plants, the members of the genus *Stapelia* have long found favour among lovers of succulent plants on account of their curious and often very beautiful flowers, and the ease with which many of the species may be cultivated. The plants are widely distributed in many parts of tropical and subtropical South Africa, and there are a large number of species. Most of these are local in their distribution and vary considerably in size, shape and colour of the flowers, stems and leaves. Although widely separated, botanically, from the Cactus family, they all have a curious Cactus-like habit and appearance, and thrive under similar cultural conditions. The flowers of most of the species are star-shaped, the tips of the petals being often reflexed, while in a rare and distinct section of the genus the flowers are large and bell-shaped, the colours being usually some shade of dark chocolate, red, brown or yellow, the ground colour being often prettily veined or marbled with yellow or creamy white. In nearly all the species the inner parts of the flowers are more or less hairy, sometimes densely so.

Although the majority of the species are somewhat shy in the production of flowers, a few, such as *S. rufescens*, *S. variegata* and its numerous varieties, *S. picta*, *S. mutabilis* and *S. grandiflora*, are the reverse and flower freely on established specimens. Some of the tropical kinds have very large flowers, those of *S. gigantea* being 12 inches to 14 inches in diameter; in others, like *S. Plantii* and *S. grandiflora*, they are 5 inches to 6 inches across. In the bulk of the species, however, especially those commonly met with in cultivation, the flowers are from 1 inch to 3 inches in diameter, these being for the most part species which require the conditions of an ordinary greenhouse, the tropical kinds being rarely cultivated except in botanical gardens and large collections formed by amateurs.

The flowers of practically all the species emit a strong and foetid odour on first opening, and in some kinds this closely resembles that of tainted meat and proves an irresistible attraction to large numbers of flies, especially the blue-bottle and house-fly. It is evident that these are deceived

by the odour into the belief that the flower will in some way provide a suitable food for the rearing of their young, for they cover the surface of the flower with numerous eggs, and the grubs that hatch from these may be seen wriggling about among the hairs and inner parts of the flower, sometimes for several days before they die. The flowers of most of the species last for about four days from the time they expand; a few species last for several days longer, but they are the exception rather than the rule. Weather conditions have a considerable effect upon their lasting properties, flowers which open during a spell of dull weather often lasting double the normal period.

Under natural conditions pollination is effected by dung-flies, and the flowers have adapted themselves in a curious way both in their structure and by emitting an odour for attracting these particular flies for ensuring cross-pollination. What the flies obtain for their trouble it is hard to say. In the whole genus the flowers

lime should be added to the soil, as they are all natives of districts and soils free from this constituent. The pans or pots in which they are grown should only contain from 1½ inches to 2 inches of this compost, the rest being filled up with good drainage material. During the growing period the plants require as much water at the roots as a *Geranium*, but, after growth has finished, the soil should only be kept slightly moist; water sparingly during the winter, but do not allow them to become so dry as to cause their succulent stems to shrivel. The atmospheric moisture should also be kept down to a minimum during this period, but air ought to be admitted to the house on all possible occasions. C. P. R.

GOOD EFFECTS WITH MIXED PLANTS.

Now that the planting of Roses, herbaceous perennials and other flowers is being done, it should

A CHARMING GARDEN SCENE CREATED BY PLANTING HERBACEOUS FLOWERS IN FRONT OF RAMBLER ROSES.

attract only to destroy, receiving the services of the fly as an agent to ensure cross-pollination, and, in return, killing—indirectly, it is true—large numbers of the young of its benefactor.

To the amateur of small means the *Stapelias* are eminently fitted for supplying a very interesting and strikingly beautiful class of plants of easy culture, and they are of additional interest, as a large number of plants can be readily accommodated in a small sunny greenhouse, as they are mostly of a dwarf, compact habit. It is surprising what a small amount of attention they will thrive under. The majority of the kinds are greenhouse plants, only a few of the cultivated species requiring tropical conditions. They may all be grown in a mixture of loam and a liberal addition of sand or broken brick rubbish. No

be remembered that often very pretty effects can be obtained by grouping one in close proximity to the other. A charming picture of this kind is shown in the accompanying illustration, where Rambler Roses, scrambling over an irregular fence, provide a pleasing background to the stately Delphiniums and the more lowly herbaceous plants grouped in the foreground. It is little pictures of this kind that add so much to the interest and beauty of our outdoor gardens, and the clever planter will seize every opportunity to bring them into being. Flowers of light colour, and also white, are greatly improved by having a dark background of evergreens. One of the most pleasing effects of this kind that we remember as a large bed of white Japanese Anemone planted in front of a dense bank of Yews and Hollies.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Melons.—If ripe Melons are desired by the first day of May, a sowing must be made now in order to have good, strong plants ready to put out by the first week in February. The seeds should be sown singly in small pots and placed in a bottom-heat of 80°. The bed for this purpose ought to be made up to within a foot of the roof glass in a warm forcing-house. When the young plants are well through the soil, they may be given support by placing a small twig to each and securing it by means of thin matting. As soon as the roots reach the edge of the pots, the plants should be carefully potted into 3-inch pots and kept quite near the roof glass in order to keep them stocky. The soil may consist of loam and leaf-soil in equal parts. Eminence and Hero of Lockinge are good varieties for this sowing.

Early Pot Vines.—If these were started in the first week of November, the buds will soon be bursting into growth, and at this stage the temperature of the house may be raised to 65° at night. When the buds have burst freely from top to bottom of the Vines, the shoots should be carefully tied to the trellis, and after a few days disbudding may be commenced, as it is a mistake to leave more shoots than are necessary to cover the trellis, or to leave more bunches than the Vines are capable of bringing to maturity. Watering must be carefully attended to, and, each time this is applied, sufficient must be given to moisten the whole of the soil. While it is necessary to maintain a moist atmosphere, steam should be avoided.

Plants Under Glass.

Cinerarias.—These plants will require very careful attention with regard to fumigation, which should take place on the first appearance of insects. If once allowed to become crippled by these pests, no amount of care afterwards can restore them to their natural beauty. A temperature of 50° is quite high enough, and frequent applications of manure-water ought to be given. Soot-water may also be applied with advantage.

Chinese Primulas.—The most forward batch of plants should now be placed in the show-house and as near the glass as possible. Very careful watering will be necessary during dull weather. The atmosphere must also be kept moderately dry. Succession plants in heated pits will benefit by a dressing of artificial manure, which may be lightly pricked into the surface soil previous to watering the plants with clear soft water; 50° at night is quite high enough for these plants.

Early Potted Bulbs will now be well furnished with roots, and may be moved into heat as it becomes necessary; but this must not be attempted until the plants have made some top growth as well as plenty of roots. Maintain a moist atmosphere and avoid a high temperature until the plants are well on the move.

The Flower Garden.

Lawns.—Where the lawn is brown and patchy, a dressing of basic slag should be applied now. As this is one of the least soluble manures, it requires to be applied in the early winter in order to get the full benefit during the following summer, and for this purpose the finest powdered sample should be selected.

The Rock Garden.—Many of the subjects will benefit by a surface-dressing as a protection from sharp frost or heavy and continual rain. The dressing may be placed so as to cast off the heavy rain as well as protect the roots from frost. The plants must be kept quite free from fallen leaves, which have a choking effect on their constitution, as well as forming a shelter for slugs and other pests.

Sweet Peas that are required for planting in March must be sown in small pots at once. Place the pots in a cold brick pit and keep a sharp lookout for mice, which may do a great deal of damage in a little time. About three seeds should be placed in a 4-inch pot. The soil may consist of three parts sandy loam and one part leaf-soil. Crock the pots carefully. The pit may be kept

closed for a time, but, as soon as the young plants appear, ventilation should be freely given. These late sown plants are a useful addition to those sown in October.

The Hardy Fruit Garden.

Fig Trees on Walls.—Some protection must be provided for these trees before sharp frost sets in. The branches should be liberated from the wall and all worthless shoots removed, after which the remainder ought to be carefully tied together and a covering of some dry material placed over them. This should be allowed to remain while sharp frost continues, but no great quantity of covering should be left on the trees after the frost is over, or the first crop of fruit will suffer in consequence. The final pruning of the trees should not take place until the branches are tied up in March.

The Kitchen Garden.

Celery.—The latest batch of Celery must receive the final earthing-up at once, but it is necessary to exercise a great deal of care to keep the plants quite free from soil in the centre, or many of them will be deformed and of little value for other than cooking purposes. If sharp frost sets in, the beds should receive some protection. Either clean straw or dry Bracken will do.

Cauliflower Plants in Pits.—These plants ought to be potted into 4-inch pots with as little delay as possible. The earliest batch will now be rooting freely, and must be kept in a well-ventilated pit. Do not allow the plants to become stunted for want of a little manure-water. The aim of the cultivator should be to keep them as stocky and short-jointed as possible.

French Beans in Pots.—Water freely with liquid manure and admit fresh air whenever the external conditions permit.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Onions.—On wet days opportunity should be taken to turn over the stock of Onions, as, no matter how carefully they have been harvested and stored, there is sure to be a few damping. If possible, give them a little more floor space.

Cabbage.—During the remarkably open weather experienced in November, weeds have grown alarmingly, and every encouragement ought to be given to the autumn-planted Cabbages by running the hoe between the rows to stir up the soil. This can only be done when the weather is fairly dry. No attempt must be made to hasten the growth at this time, by the use of fertilisers. These should only be applied when growth commences in the early part of the year.

Parsley.—So far there has been no difficulty in obtaining supplies from the open borders, and where this has not been checked by severe frosts it will be advisable to have it protected in some way. A simple method is to secure some Ash suckers and bend these over the rows hoop fashion at intervals, and over these ordinary sacks or garden mats can be laid on the approach of frost or snow. This method I have found to be very effective. Plants that are growing in frames should be given abundance of air, except during very severe weather.

Tomatoes.—The plants intended for an early spring supply of fruit ought now to receive their final potting. In doing so, just use sufficient soil to cover the ball, leaving room for top-dressing from time to time. These plants should occupy a position near the glass in a temperature not exceeding 55°. Water must be given with caution; indeed, if the soil was moderately moist when potting, no water will be required for a time.

The Flower Garden.

Planting.—The planting of all trees and shrubs should be proceeded with on all favourable occasions, especially when large specimens are to be transplanted. The transplanting of Hollies and Bamboos, however, must be deferred till at least the month of May, and in some districts even as late as June.

Roses.—Where a large number of wall and pillar Roses are grown, the work of cutting out some of the old shoots may be proceeded with. This will save time during the busy spring season. In the case of Crimson Ramblers it will be advisable to leave rather more shoots than are required to furnish the pillar, as, owing to the softness of the wood, many may yet be destroyed by frost. Planting must also be proceeded with when weather conditions permit. Although it is difficult to get the soil sufficiently dry at this season, planks can be used to stand on, which will lessen the effect of binding the soil.

Dahlia Tubers.—On the approach of severe weather these tubers should be carefully examined, and if the slightest sign of damping is seen, an additional covering ought to be given. I find there is nothing better for keeping the tubers sound than some sifted soil or sand worked in among them.

Plants Under Glass.

Gardenias.—To prolong the flowering season of this fine stove plant, a batch of cuttings inserted now should come into bloom early next autumn. Place these cuttings in a propagating-case where a good bottom-heat can be kept up. Older plants must not be subjected to an excessive dry heat, which encourages mealy bug, an insect that is particularly partial to Gardenias.

Clivias.—A few plants that have been standing in rather cool quarters may now be placed in a warm house, where they will soon throw up their flower-spikes. These will be especially welcome about the New Year as a change from Chrysanthemums. To increase the stock, a few of the older plants should be broken up; but as the roots will be found to be matted together, the work of dividing will be no easy task. Place the young plants in a heated house and water sparingly for a time.

Roses.—A batch of pot Roses should now be prepared for forcing, afterwards standing them in a light, airy house and bringing them on very gradually. Indeed, unless the weather is unusually cold, little or no fire-heat will be required for a time. If the plants have not already been pruned as previously advised, this must be done before placing them inside. The drainage should be examined and the pots thoroughly washed. All these details tend to a healthy growth.

Carnations.—To keep up a supply of blooms at this season of the year is no easy task, and, to avoid damping of the blooms, a little more artificial heat ought to be given, together with careful ventilation. To encourage the growth of strong stems, it will be necessary to reduce the flower-buds to one on each stem.

Lily of the Valley.—To have a supply of flowers for Christmas from retarded crowns, the forcing must commence at once. On no account place them in excessive heat at the start; rather should the forcing be gentle until the growth is fairly well advanced. For furnishing purposes the aim should be to have well-developed foliage, which will the better show the flowers to advantage.

The Hardy Fruit Garden.

Morello Cherries.—The nailing and training of these Cherries is a long and tedious job, and no opportunity must be lost in pushing this work forward when the weather is at all favourable. Some of the older trees should be completely overhauled by cutting away old and useless shoots, retaining only those that are young and fruitful. When the work of training is completed, some turfy loam and well-rotted manure ought to be lightly forked in round the tree, or, if this is not possible, a top-dressing of the same material will answer the purpose as well.

Fruit Under Glass.

Peaches.—The forcing of permanently planted Peaches is a task that requires to be very carefully performed, especially in the earlier stages of growth. Trees that have been forced for a number of years may safely be started now. The house should be closed down, and, unless the weather is more severe, no fire-heat ought to be given for at least a fortnight; indeed, a high temperature should at all times be avoided. If the border is at all dry, only tepid water ought to be given; but if the border was attended to in the autumn, no water should be required.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hoptoun Gardens, South Queensferry, N.B.

CULTIVATION AND COLLECTION OF MEDICINAL PLANTS IN ENGLAND.

[The following has been recently published as Leaflet No. 288 by the Board of Agriculture.]

(Continued from page 582.)

HENBANE (HYOSCYAMUS NIGER, L.).

Prospects.—This biennial is cultivated in this country for extract making. There is a limited demand for this purpose, and the established drug farms will probably be able to meet it. The official Henbane leaves of the British Pharmacopœia are the leaves and flowering tops of second year plants of biennial Henbane, but the dry commercial leaves imported from Germany and Russia are derived from the wild annual. The plant might be grown next year to make good any shortage, if good germinable seed can be obtained. There will be a demand for dry leaves at enhanced prices next year

The normal price of the Continental drug plant is 40s. to 45s. per cwt. The English-grown plant is ordinarily worth 3s. to 6s. per lb.

Cultivation.—Henbane grows in similar situations to Belladonna, and its cultivation is much the same. The seeds, however, are prone to lie dormant, and the crop is tricky and uncertain, sometimes dying in patches. Commercial Henbane seed is often kiln-dried and useless for sowing. The annual variety is smaller and does not branch so freely as the biennial plant, so that it may be sown in rows 18 inches apart, and the biennial 2 feet to 2½ feet. The leaves (flowering tops) are gathered when the plants are in flower (biennial, June or July; annual, August). The root is not used in medicine. The fresh leaves lose 80 per cent. of their weight on drying.

"EGYPTIAN HENBANE" (DATURA METEL, L.).

This plant is a valuable source of the mydriatic alkaloids hyoscyne, hyoscyamine and atropine. It may perhaps be grown in the same way as Thorn Apple.

OPIUM POPPY (PAPAVER SOMNIFERUM, L.).

Prospects.—The white variety of the Opium Poppy is still grown in several parts of the country, notably Lincolnshire, for the sake of its capsular fruits. The crop is always a precarious one, but there is a steady market for Poppy heads. Belgium usually supplies a proportion of the Poppy heads used in this country, but not sufficient for the loss of her crop to cause serious shortage next year. The price paid for Poppy heads is 12s. to 15s. per 1,000 for large size, and 8s. to 10s. for medium.

Cultivation.—Poppies prefer rich, moist soil with plenty of sun, and the usual practice is to take a crop after Wheat, Oats or Barley. The land is manured and ploughed in autumn to ensure a fine tilth in spring. Sowing is done at the end of March or in April, according to weather, allowing 1lb. of seed per acre and drilling in rows a foot apart. The whitest seeds are preferred. Plants which are too forward are liable to be cut down by late frosts, while, if seed is sown too late, the seedlings may become dwarfed if dry weather sets in before they become well established. A light roller is sufficient to ensure the seeds being covered.

When the plants are 3 inches or 4 inches high they are cut with a hoe into clumps

about 6 inches to 9 inches apart, and are afterwards "singled" by women or children, leaving a solitary strong plant from each group. Weeding is necessary. A dressing of soot or fertiliser may be given if support appears to be needed.

Poppy heads of pale colour are most desired, but a week's rain or even a few nights' heavy dew may spoil the colour of the ripening fruits. High winds and heavy rains are dreaded, as the plants become top-heavy. The capsules are harvested by women or children about September; they are broken off and placed in baskets, and are transferred to sacks to be conveyed to the drying floor. The yield is very variable. The drying floor is a boarded floor in a freely ventilated warehouse, and on it a thin layer of capsules is turned each day by shuffling the feet along the floor. The capsules usually take a fortnight to dry.

THORN APPLE (DATURA STRAMONIUM, L.).

Prospects.—The Thorn Apple is not grown on a commercial scale in this country. The principal use of the drug is as an ingredient in burning powders for asthma, considerable quantities of the wild leaves being imported from Germany and Hungary. The normal price of foreign Stramonium leaves is about 40s. per cwt., but 80s. has been asked since the outbreak of war. The seed is also a commercial article, but demand is very limited. The plant is an annual and easily

grown. The dry leaves would find a ready market next year.

Cultivation.—The seeds (10lb. to 15lb. 1 acre) are drilled in rows 2 feet apart. The plants grow well in sunny situations. The crop is cut with the sickle when in flower in late summer. The leaves are stripped off and dried as quickly as possible, usually by artificial heat. About thirty-four parts of dry leaves are produced from 100 parts of fresh leaves. The thorny capsules are gathered from plants allowed to stand, when full grown but still slightly green. They split and shed their seed on drying.

Datura Tatula, L.—A closely allied species with purple flowers (not white as in *D. Stramonium*) is occasionally used in medicine in place of *D. Stramonium*.

VALERIAN (VALERIANA OFFICINALIS, L.).

Prospects.—Valerian is common in England in moist situations. Most of the drug plant of commerce consists of rhizomes from plants grown in Derbyshire, or imported from Holland, Germany and France. The foreign root was selling in January at 30s. per cwt., English being worth 1s. to 1s. 3d. per lb., about four times that price. Very little Valerian is now cultivated in this country, and great scarcity already exists. Abnormal prices will be paid for some time to come.

(To be continued.)

EARLY FLOWERING CHRYSANTHEMUMS.

THE sub-committee of the floral committee of the Royal Horticultural Society met at Wisley on September 25 and October 16 and made the following recommendations for awards, which were confirmed by the floral committee and approved by the President and Council on October 20:

Numbers.	Name of Variety.	Sent by	Results in previous year.			Award now recommended.
			Date.	Sender.	Award.	
165, 501	Almirante	Jones, Wells				
39, 138, 529	Champ d'Or	Barr, Jones, Wells				
497	Evelyn	Wells and Co.				
31, 93, 296, 536	Fée Parisienne	Barr, Dobbie, Jones, Wells				
56	*F. Wilson	Simpson				
329, 483	J. Bannister	Jones, Wells				
496	Jimmie	Wells				
250, 472	Lorraine	Jones, Wells				
162	Martin Peed	Jones				
75, 300, 485	†Mrs. J. Fielding	Dobbie, Jones, Wells				
274, 513	†Goacher's Terra Cotta	Jones, Wells				
527	Mabel Roberts	Wells				
88, 252, 517	Mrs. W. Sydenham	Dobbie, Jones, Wells				
58, 538	Pluie d'Argent	R. Veitch, Wells				
19, 106, 309, 444	Roi des Blancs	Barr, Dobbie, Jones, Wells				
52, 208	R. Pemberton	Barr, Jones				
102	Stella	Dobbie				
127, 432	Tonkin	Dobbie, Wells				
74, 158	Caledonia	Dobbie, Jones				
65, 537	Abercorn Beauty	Dobbie, Wells	15-9-10	Dobbie	A.M.	Previous aw'd confirmed

ANSWERS TO CORRESPONDENTS.

TREES AND SHRUBS.

MOVING LARGE BOX PLANTS (C. E. M.).—The Box plants which you propose to move to fill up your hedge ought to transplant quite well, providing ordinary care is exercised in their removal. If you are not in a hurry to fill the gap, it would be advisable to leave the work until April: then remove the plants with as much soil attached to the roots as possible. Keep the plants well watered next year, and give the roots a surface-dressing of leaves and manure in the event of dry weather being experienced.

VALUE OF ARAUCARIA WOOD (Mrs. F. E. R.).—The timber of *Araucaria imbricata* (Monkey Puzzle) is useful in its native country, but it has no special commercial value here on account of the limited supply. Trees of this description are often sold at the price of firewood. At the most it is doubtful whether such a tree would realise more than sixpence a cubic foot, for, in addition to there being no regular supply of the timber, the wood from ornamental trees is usually very knotty. You could have it cut up for home use, for it would do for general indoor finishing of houses or outhouses, fencing or other uses for which ordinary deal is employed. It is probable that if the tree were grown for timber under sylvicultural conditions in this country, some considerable use would be found for the timber.

KITCHEN GARDEN.

TO PLANT A SMALL VEGETABLE GARDEN (B. A.).—You do not say what sort of land it is which you are going to make into a vegetable garden, whether the soil is heavy or light, shallow or deep, whether it has been cultivated before or not. Had you given us a few particulars such as these, we could possibly have rendered you a better service. After forming your walks, trench the ground at least 2½ feet deep, and if there are any coarse weeds or grass on the surface, bury it in the bottom of the trench. Apply at least half a cartload of rotted farmyard manure to each rod or perch of land, mixing it with the soil as trenching proceeds. Plant bush or pyramid Apple and Pear trees on either side of the walks all round the garden, at distances apart of 10 feet and 4 feet away from the walks. Plant a Currant and a Gooseberry bush between the trees. Border No. 1 plant with Strawberries and Raspberries. Border No. 2 plant with Loganberries. Borders No. 3 and 4 devote to early crops of Potatoes, Cabbages, Peas, Lettuce, Cauliflower and Turnips. Quarter No. 1 devote to Potatoes. Quarter No. 2 devote to later Peas, Cauliflower, Carrots, Parsnips, Beetroot, Celery, Onions, Brussels Sprouts, Broccoli and winter greens generally. Plant Cabbage, winter Lettuce, and autumn-sown Onions now. Seakale (root cuttings) can also be planted now. Now is a good time to plant all the fruit trees. If you will let us know how many trees of each sort you propose to buy, we will give you the names of the best sorts.

FRUIT GARDEN.

APPLE FOR INSPECTION (Miss I. R.).—The Apple is affected with the trouble known as bitter-pit. This disease is of physiological origin, not due to any parasite, and appears to depend a great deal on the weather. We think it is connected with failure of the water supply at a critical period of growth, and recommend you to see that the water supply is regular and sufficient.

MISCELLANEOUS.

CLOVER IN GRASS (Enquirer).—The best means of destroying Clover in grass is to encourage the grass by giving suitable manures so that it will outgrow the Clover. Try a dressing of superphosphate and nitrate of soda or sulphate of ammonia at the rate of 3lb. of superphosphate to 1lb. of nitrate or sulphate of ammonia per rod. Apply the manure evenly during moist but not very wet weather.

TREATMENT OF TENNIS LAWN (Mrs. A. A.).—The fault of your tennis lawn is that it was originally laid either on ground full of weed seeds or with weedy turf. Some weeds can be destroyed by dressing them with sulphate of ammonia, but it is doubtful whether it will kill Plantains without permanently injuring the surrounding grass. The Plantain has a deep, vigorous rootstock, from which new crowns spring, although the top may have been killed. The best way to get rid of Plantains is to keep pulling them up and encourage the grass to thicken by every possible means. A good dressing of basic slag will encourage the grass. Soil is also a good dressing to apply to a lawn, but it must be free from seeds of weeds, which thrive in grass. When once a lawn becomes infested with Plantains, it takes several years to clean it, for seedlings continue to appear. Do not mow it without a collecting box to the mower after the weeds begin to flower. We advise you to have the Plantains and other coarse weeds pulled up; then apply a dressing of one of the lawn sands which are at present on the market. A week or so afterwards give a dressing of good soil and basic slag, which should be evenly distributed, care being taken to fill all holes left by the extraction of the weeds.

NAMES OF FRUIT.—P. A. G.—1, Warner's King; 2, Annie Elizabeth; 3, Malster; 4, Tom Putt; 5, Marie Benoit.

NATIONAL DIPLOMA IN HORTICULTURE.

GARDENERS are reminded that in 1913 a Professional Diploma was established with the consent of His Majesty's Government, and as the outcome of an arrangement with the Board of Agriculture. Under such arrangement the diploma was to be (a) styled "National," (b) strictly confined to the members of the gardening profession, and (c) secured by examinations of both a practical and theoretical nature. Among those for whose benefit the diploma was established are the following: Florists, fruit-growers, gardeners, horticultural inspectors, horticultural instructors, landscape gardeners, market gardeners, nurserymen, public park gardeners, and seedsmen. The first Preliminary Examination was held in June of this year, when over sixty candidates presented themselves. A large proportion of these have already entered their names for the first Final Examination, to be held in June, 1915, when there will also be a further Preliminary Examination.

Winter affords to gardeners the time for study which the longer days of spring and summer deny them. Their attention is therefore particularly called to the opportunity of the present months and the distinction which the diploma confers as the highest evidence of proficiency in the craft. It will undoubtedly become more and more recognised by employers as an indication of the ability of those who hold it as years pass along. It raises the rank of the gardener in the profession—a point of great value.

Candidates can register themselves for the examinations after they have attained the age of nineteen. The Preliminary Examination can be taken after the age of twenty-one is reached, not less than four years having been spent in the practice of horticulture. The Final Examination is open to those who have passed the Preliminary Examination and have spent not less than six years in horticulture.

Young gardeners, particularly, are urged to consider the desirability of registering themselves, and of applying themselves to the necessary practical and theoretical work forthwith. From the testimony of the candidates of June last it is abundantly evident that the effort involved proved of great value to them. The examinations are not only a stimulus, but preparation for them necessitates definite work upon systematised lines, according to the candidate's sphere in the profession.

Forms of application for registration, with a syllabus of the examinations, can be had from the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W.

SOCIETIES.

BOLTON AUTUMN SHOW.

THE exhibition this year was, as usual, held in the Town Hall on the 20th and 21st ult., and although this locality is suffering somewhat harshly in consequence of the war, it was decided to carry out the arrangements of the show with a reduction in the prize money, any balance arising out of the show to be handed over to the National Relief Fund. The exhibitors ungrudgingly supported the efforts of the executive, the result being a show well up to former efforts, while a number of ladies gave their services in disposing of flowers, fruit and plants which had been presented for the purpose, so that it is hoped the results financially may be satisfactory and a liberal sum handed over to the above-mentioned fund.

The cut Chrysanthemums were fully up to the average, and it is questionable whether the thirty-six Japanese set up by Mr. C. Jones, Abergele, were not the finest yet seen in the Town Hall. The whole of the blooms were remarkable for their even form, size and freshness. His Majesty was a grand bloom, Queen Mary immense,

while a sport from this variety looks most promising, being broader in petal, of good substance, and of the same purity as the type. Mr. A. Chandler, gardener to Arthur James, Esq., Rugby, was a good second, his Queen Mary being extra large.

For twenty-four blooms, twelve incurved and twelve Japanese, Mr. A. Chandler improved his position mainly through his incurved, which were notable for compactness and finish; this stand proved that this section is still worthy of a place. Mr. J. Copple, gardener to J. Bell, Esq., Huyton, was second with larger incurved blooms, but they lacked the finish of the former.

For six vases of singles, ten blooms in each vase, Mr. Loo Thomson, Formby, won the coveted position with grand blooms, but not approaching coarseness. Mr. W. Byrom, gardener to the Earl of Ellesmere, Worsley, was second with good flowers.

In the six vases of undisbudded blooms, Mr. A. Porter, Cheadle, was in strong evidence with immense masses of well-coloured flowers. Mr. J. Nixon, gardener to O. Robinson, Esq., Alderley Edge, followed.

The circular basket brought a pleasing display, the blooms being set well apart and improved by added foliage. Mr. J. Nixon was especially happy in his set, Croton and Asparagus foliage adding greatly to the charm. Mr. A. Adshad was second with good flowers.

One vase of Carnations brought some lovely blooms, Mr. J. E. Elliot, gardener to T. D. Grimshaw, Esq., Burnley, and Mr. J. McGregor being placed as named.

Groups are always a strong feature, and the show under review was no exception as regards quality. Mr. H. Shone, gardener to J. W. Makaut, Esq., Gilnow Lodge, Bolton, although not in the realms of competition, occupied the centre of the hall with a large circular group, which did him much credit, both for the quality of the material and for the tasteful manner in which it was arranged, his abundance of *Cattleya labiata* and well-grown *Bertolonias* proving valuable adjuncts.

The group of undisbudded Chrysanthemums in half-circular form brought two competitors, who both staged fine banks fully 10 feet in height with bright flowers, the first prize group, shown by Mr. Ben Hardy, gardener to G. S. Peck, Esq., being a little brighter in colour than that exhibited by Mr. D. Wilson, gardener to Miss A. M. Phillips, Prestwich.

For the mirror group Mr. H. Wainwright, gardener to Mrs. Charles Taylor, Heaton, was the first and only competitor, in which his material was staged to advantage.

Mr. M. Hodgson, gardener to E. Timberlake, Esq., Worsley, led the way for three Orchids with choice varieties, Mr. J. Ramsden having the leading single plant.

Mr. H. Wainwright won the leading place in three classes for Chrysanthemums in pots.

Mr. W. Austin, gardener to Lever Tillotson, Esq., took four firsts for Begonias, Cyclamen, Roman Hyacinths and a specimen Palm.

Mr. A. Porter, Cheadle, had the leading dinner-table plants.

The numerous other classes were well filled, the Chrysanthemums in vases being excellent, but details of these cannot be given owing to lack of space. The arrangements throughout were highly creditable to those concerned.

BIRMINGHAM AND MIDLAND COUNTIES GARDENERS' ASSOCIATION.

FLOWERING TREES AND SHRUBS FOR GREAT BRITAIN. OWING to the regrettable absence of the chairman (Mr. Herbert), Mr. J. Higley presided on Monday evening, the 16th ult. After the minutes of the preceding meeting had been read and certified, Mr. W. Spinks, the treasurer and an old and much esteemed member of the association, gave an instructive and comprehensive "chat" on "Flowering Trees and Shrubs." The purpose of the "chat" would, he hoped, be achieved by its finally resolving itself into a free discussion, into which he accordingly invited all who wished to enter. In opening, he confessed that this was a subject of which he had always been very fond, and, in view of his great enthusiasm for it, it is only fair to state that perhaps no other arboriculturist in or around Birmingham to-day could look with more meritorious pride on the splendid improvements wrought by his efforts in this direction, for many beautiful specimens of trees and shrubs existing both in city and suburban gardens in this district were planted under his direction. When arranging a new garden, trees and shrubs are usually considered with the object of beautifying any particular space requiring it. With newly planted trees it is a serious mistake to withhold the full amount of requisite attention, as most likely several years would probably elapse before any neglect at the time of planting or mulching could be overcome. Again, too, in the case of pruning—unlike the samples now exhibited in many of our public parks—the art of this craft consists in keeping the cutting so beneath the leaves that the cuts themselves could hardly be discernible. In this way the trees themselves thus have a natural appearance. There are at present about 1,400 varieties of trees and shrubs in existence, and, of course, all could not be dealt with in a single "chat." Mr. Spinks, therefore, took the most important. These he classified in the following manner: (1) Large flowering shrubs of an ornamental character; (2) the smaller or free-flowering kind; (3) the evergreen; and (4) those of a deciduous nature. In each case the speaker gave a full and well-selected list, contributing to each single plant contained therein a few brief remarks as to its habits and its cultivation, divulging by this means much useful information. That the "chat" had more than attained its object was fully evident by the brisk alacrity with which several members responded to the ensuing discussion. The customary, but none the less appreciative, vote of thanks was proposed by Mr. Cryer and ably seconded by Mr. Palmer.

THE GARDEN.

No. 2247.—VOL. LXXVIII.

DECEMBER 12, 1914.

NOTES OF THE WEEK.

Carnations for the Belgian Relief Fund.—We are informed that the total amount realised at the auction sale kindly conducted by Mr. E. Prothero at the close of the Perpetual Flowering Carnation Society's London Show on Wednesday of last week was £19 18s. 6d. Considering the few people who were present, this amount, which is for the benefit of our Belgian friends in this country, is fairly satisfactory. Had the sale been more widely advertised, no doubt the sum would have been considerably augmented.

Horticulture in Ypres.—It was with mixed feelings of sympathy and pleasure that we renewed our acquaintance, at the Carnation show held in London last week, with Mr. V. Bouckennooghe of Ypres. Mr. Bouckennooghe, as an Old Kewite, is well known to many horticulturists in this country, who will be grieved to hear that his nursery at Ypres is practically ruined. The large Carnation house, in which flowers and plants were grown for market, has been demolished by four German shells, which exploded in or near it, and practically the whole of the outdoor nursery is pitted with huge excavations caused by shells. Mr. Bouckennooghe, who is now staying in this country for some little time, speaks in the highest terms of our soldiers who are fighting in the Ypres district, and also of the kindness extended to him and his family by horticulturists and others in this country.

A Good Winter Cherry.—Although we are not greatly enamoured of dried plants, we must make an exception with the beautiful Winter Cherry named *Physalis Bunyardii*. Its two parents, *P. Franchetii* and *P. Alkekengii*, are known in most gardens where hardy plants are grown, but *P. Bunyardii* is a decided improvement on both. The curious balloon-like capsules are large and of brilliant scarlet hue, while the stems often attain a height of nearly four feet. If cut about the end of October and gradually dried, the capsules retain their colour throughout the winter. The fruit inside the capsule resembles a small Tomato or, externally, a Cherry, hence the popular name. This hybrid was raised by the late Mr. Fry of Addington, near Maidstone, and sent out some years ago by Messrs. George Bunyard and Co. The plant will thrive in almost any kind of soil, but as it spreads

rather rapidly, it ought not to be planted close to slow-growing choicer plants.

Chrysanthemums for War Funds.—At the Stevenage, Herts, Chrysanthemum Show held recently, the whole of the proceeds, amounting to over £50, were devoted to providing tobacco and other comforts for the men of the Hertfordshire Regiment now at the Front. For a small town such as Stevenage the result is highly creditable, and we cannot imagine a better cause to which flowers could be put at the present time.

Saponaria ocymoides.—For mantling rock and shrouding it for a period of weeks in the summer-time there is perhaps no easily grown alpine plant more desirable than this rosy-coloured Soapwort.

possible culture, reproducing itself freely from seeds, and is the more precious because of the fact. These may be sown in the earliest days of the year. Cuttings of the fresh young shoots also root freely in late summer or in early spring, and these are necessary in the case of varieties.

Late-Fruiting Thorns.—When planting Thorns it is as well to bear in mind those that retain their fruits late in the season, as there is considerable difference among them in that respect. *Crataegus Carrièrei*, a beautiful tree with large orange fruits, the leaves also remaining on the tree after other trees are bare; *C. prunifolia*, an attractive variety of *C. Crus-galli*; and *C. durobrivensis*, one of the American Thorns, are some of the best. These are very conspicuous at the present time, when the majority of Thorns are quite bare.

Resignation of the Rev. David R. Williamson.—Many flower-lovers, and among them our readers, will learn with regret that the Rev. David R. Williamson, minister of Kirkmaiden, Wigtownshire, and a frequent writer in **THE GARDEN**, has resigned his charge on account of failing health. Mr. Williamson has for years devoted special attention to Roses, Lilics and Sweet Peas, and his collection of these at Kirkmaiden and reflections thereon have been the theme of many pleasantly written notes. Mr. Williamson is also devoted to music and poetry, and has the acquaintance of many of the leading artists in the musical world. His poems, such as his best-known works, "Poems of Nature and Life," show poetical abilities of no mean order.

Sternbergia lutea angustifolia.—A rock garden should not be without a group of this beautiful plant. Flowering as it does in the autumn with such bulbs as *Zephyranthes*, *Colchicums* and *Crocuses*, it adds a note of warm yellow, which the others all lack, to the rock garden. Beautiful as is the type, the variety *angustifolia* is preferable, as it appears to be hardier, and certainly blooms more freely. It should be planted in a warm spot in well-drained soil, and where it will remain undisturbed. A large clump of it has been flowering in our garden now for over two months, and is still producing its large, bright yellow, Crocus-like flowers above its dark green foliage.

SAPONARIA OCYMOIDES, A DWARF SOAPWORT WITH ROSE-COLOURED FLOWERS.

Inhabiting Central and Southern Europe in the wild state, chiefly in stony and rocky places, and sheeting these with an array of blossom impossible of description, the conditions of its home life afford a clue to its garden requirements, and it is in these probably, or the nearly related conditions of wall garden or ruins, that the plant is most prodigal of flowering. By reason of its trailing, prostrate habit of growth it is well suited for high-placed positions, and given a deep root-run—half soil, half stone—in crevice or cranny, its greater luxuriance is suppressed and a meandering stream of colour several feet in extent the net result. Happily, the plant is of the simplest

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Regelio-Cyclus Irises.—I have read with considerable interest the very lucid and instructive article by Mr. E. H. Jenkins on this subject which appeared on page 575 of your issue dated November 28. Mr. Jenkins' success with these charming plants will, I am sure, induce many other readers who, like myself, have tried and failed, to try them again, and if only a small measure of the success that he has obtained falls to my share I shall feel more than grateful to this veteran writer. In the past, through studying carefully his articles in *THE GARDEN*, I have derived much valuable information, and I hope he will long be spared to give readers the benefit of his wonderful store of knowledge.—T. T.

Crocus susianus.—I was very pleased to see the appreciative note about this charming little Crocus on page 567 of *THE GARDEN* for November 21. I can fully endorse all that is said in its favour there. Last year, owing to unavoidable causes, some corms of this species could not be planted until the second week in December, yet towards the end of February they gave us a glorious display of rich yellow, chocolate blotched flowers. Hence those who have not yet planted some need not fear that it is too late to do so now. Another charming Crocus that ought to be much more widely known than it is at present is Sieberi. With me it flowers at about the same time as *susianus*, or perhaps just a little earlier, and its dainty lavender blue flowers, with their vivid orange stigmata, never fail to elicit high praise from gardening friends.—EAST HERTS.

How to Plant Crinum Powellii.—I recently bought some bulbs of *Crinum Powellii* and planted them according to the directions given in Mr. William Robinson's "The English Flower Garden," i.e., "the top of the bulbs 6 inches deep," to avoid the risk of frost. To my horror I afterwards read in the cultural directions issued by Mr. Van Tubergen, jun., as follows: "Their long-necked bulbs must not be buried too deep . . . one-third of the bulb must remain above the surface." A well-known English nurseryman's catalogue says, "but are the more secure from injury by frosts if the bulbs are buried 12 inches deep." Yet another catalogue tells me they should be planted 6 inches to 8 inches deep. There is no dispute as to where the bulbs should be planted or as to the compost for them, but Mr. Van Tubergen's advice is entirely opposed to that offered by the others quoted. Will some of your readers who have grown *Crinum Powellii* successfully kindly tell me the method they have adopted? I have a lively recollection of the glorious specimens I saw in the late Sir Trevor Lawrence's garden some years since. Would that I could learn how they were grown at Burford!—ENQUIRER.

Berried Shrubs in Autumn.—The interesting note by "S. X." on page 545 induces me to say that *Cotoneaster adpressa* (syn. *congesta*) never fruits with me here, although it flowers freely and is remarkably pretty. The others I grow, such as *C. horizontalis*, berry freely. An interesting and pretty little shrub not nearly enough grown is the Pearl

Berry (*Margyricarpus setosus*), which is of trailing habit and only a few inches high. It has dark green foliage, and among this are the white, pearl-like berries which give it its name. It is still in fruit as I write this on November 25, and looks well trailing over the stones of the rock garden. The *Pernettyas* are also excellent, and I was much struck with the beauty of some plants in the rock and water garden of Mr. E. A. Hornel, Broughton House, Kirkcudbright, the other day. The best-coloured *Pernettyas* are very fine, and when the plants are a foot or so high and with a good supply of berries in good clusters, are exceptionally fine in October and November.—S. ARNOTT, *Dumfries*.

Cuttings with "Heels."—I was pleased to see that your correspondent Mr. E. H. Jenkins, in his note on "Propagating Perpetual-flowering Carnations," states that he gave up the "heel" cutting some years ago in favour of the joint-made one, the latter making much the better plant. Why we are so continuously told to take off

SKETCH OF THE ROOTS OF A ROSE BUSH ATTACKED BY CROWN GALL, AND SENT TO US BY MISS JEKYLL.

cuttings with a heel of the old wood, not particularly with regard to Carnations, but indoor plants in general, I cannot imagine, unless each one blindly follows an old, but now generally exploded, idea. That the heel of old wood, in nearly every case if not all, greatly retards the action of rooting is now well recognised by those who keep their eyes open. What is more, the young plants when struck do not grow away with the same amount of freedom as cuttings formed entirely of the young shoots. The heel of old wood or slip of the cottager is a survival of the practice of our forefathers, who, in striking even soft-wooded cuttings such as Fuchsias, always considered a joint at the base as absolutely necessary. Now, by so cutting a shoot that the bare space below a joint is allowed to remain on, and inserting it in the soil up to the pair of leaves, it roots freely. By this means practically double the quantity of cuttings are obtained—a very important matter in the case of expensive novelties.—H. P.

Crown Gall on Rose Root.—Occasionally I have seen at the root of a Rose a small, knobby lump, but have never seen so large an example as on the root of a Jersey Beauty just taken up. The mass is an irregular ball $3\frac{1}{4}$ inches in diameter at the widest part. It looks like an accretion of granules such as appear at the callusing of a cutting. It feels not quite hard, but spongy-woody. The plant is a two year old cutting. The wood of the last season's growth and the roots appear healthy. It may interest others of your readers besides myself to know the name and life-story of this abnormal growth.—G. JEKYLL. [The curious spongy swelling on the Rose root is a gall which Dr. E. Smith of Washington has shown to be due to the attack of a bacillus called *Bacillus tumefaciens*, and commonly called crown gall. The disease is a peculiar one, in that a great number of different plants are liable to attack, including Apple (on which we have often seen it), Loganberry (on which it is quite common), Birch, Cherry, Peach, Rose, *Chrysanthemum frutescens*, Carnation and numbers of others. The actual harm done to the plant does not appear to be great, at least in many cases, though, especially in America, the disease is looked upon with a great deal of suspicion. The bacillus is no doubt quite commonly distributed in the soil, and probably attacks plants mainly through small wounds.—ED.]

Autumn-flowering Plants for the Rock Garden.—In the concluding sentences of her interesting article in *THE GARDEN* of November 28 on "Preparing a Rock Garden for August and September," "K. L. D." says: "A longer list might be given if other miscellaneous plants were included; but it is already long enough to show that the rock garden in August and September need not be lacking in flowers"; while in the body of the article she also says: "It must always be borne in mind, however, that locality, North or South, makes all the difference in time of blooming." To take the last first, it is doubtless perfectly true to a certain extent, but not to any extreme extent. For instance, it is not sufficiently dominant to make a summer-flowering plant in the South into an autumn-flowering one in the North. It may modify, to some extent, its flowering period over a week or so; certainly not much longer. Situated in the middle of Yorkshire, on tableland

400 feet above sea level, open to every wind that blows from north, east, south or west, I do not suppose there is more than a week's difference between plants in Sussex and here; therefore it is with the greatest pleasure I beg to supplement her excellent list of plants for the autumn season. Without trespassing on ground already covered, I would mention, in addition, the following good autumn flowers. First, foremost and indispensable is *Verbena chamædryoides*. There is nothing either at this time or any other to compare with its mass of pure, glowing scarlet; falling over the face of a large stone, as I have had it here, 4 feet square, the effect was simply glorious, and continued so for weeks. It came through last winter quite safe, although the thermometer went down to 2° below zero in March, so I think its hardiness is assured. "providing always," as the lawyers say, that it is planted in such a position that no moisture can cling round it during winter; therefore plant it well up on the rock garden in good sandy loam and plenty of chippings mixed among it, with a

good big stone to ramble over, and you have a pure delight in store. *Veronica Lyallii*, a squat little shrubby *Veronica*, with white flowers, is also a first-class plant for this time of the year, and *V. rupestris* is too well known to need any booming, but, planted in a good mass, its sheets of lovely blue are most effective. *Androsace Leichtlinii* and its variety *oculata* are also to be relied upon for a long and lasting display, while the *Campanulas* give us many good things in addition to those mentioned. *C. muralis* is a fine, true autumn bloomer, as are *C. pulla*, *C. pulloides*, *C. Profusion*, *C. haylodgensis*, *C. G. F. Wilson*, to say nothing of the *garganica* section, *C. g. alba* and *C. g. hirsuta*, and *C. rupestris*; and most valuable is the new variety, *W. H. Paine*, which has been a treasure for weeks; *C. carpatica alba*, *C. Raineri*, *C. Scheuchzeri* and its white variety, all of which are splendid for August and September. The *Heaths* are invaluable, but have been well dealt with by "K. L. D.," so may be passed by me, but the *Potentillas* cannot be omitted. *P. formosa*, pink; *P. Willmottæ*, cherry red; *P. Tonguei*, a lovely orange, one sheet of bloom; and *P. fulgens*, silvery grey foliage and golden strawberry flowers, are all worth a place. *Viola gracilis*, *V. g. lutea*, *V. Purple Robe*, *V. munbyana*, *V. cornuta*, *V. c. alba*, *V. c. purpurea*, *V. c. Violet Queen*, *V. Papilio*, *V. floribunda*, *V. bosniaca* and a host of other very beautiful hybrids and varieties that our friend Mr. Hayward can tell us about (and I hope he will) can all be pressed into service. Then, as well as *Linaria alpina*, with its rich purple, orange-blotched flowers, there are *L. a. rosea* (equally charming, in pink), *L. repens*, *L. pallida* and *L. p. rosea*, all good, thrifty growers and flowerers. *Mimulus Ruby*, *M. Brilliant*, *M. cupreus*, *M. Burnatii*, with *M. Lewisii* and *M. cardinalis* for the damp places. *Oenothera pumila*, tiny yellow; *O. mexicana*, pink; with large-flowered *O. macrocarpa*, are all useful. *Oxalis enneaphylla*, *O. floribunda*, *O. arborea rosea*, &c. *Geranium sanguineum*, *G. lancastriense*, *G. Traversii* and *G. wallichianum*, purple, pink and blue, all good things for this season. *Pentstemon glaber*, *P. alpinus*, *P. heterophyllus* and *P. Bridgei*. *Dianthus barbatus magnificus*, the old double crimson Sweet William, can be depended upon to be one sheet of crimson, and *D. petraeus*, *D. Carthusianorum*, and *D. Wimmeri* all follow on after *D. alpinus*, *D. neglectus*, *D. cæsius*, &c., are done. *Hypericum fragile*, *H. empetrifolium*, *H. alpinum* and other varieties take their places. *Sedum Sieboldii*, *S. kamschaticum*, *S. leibmannianum* and *S. spurium*, in white, pink and crimson, all add their quota; and other things to be briefly named are *Wahlenbergia vinæflora*, blue; *Scutellaria indica japonica*, mauve; *Primula capitata*, bloomed with me for months; *Asperula suberosa*, pink; *Prunella rosea superba* and *P. webbiana*, most valuable autumn bloomers. *Corydalis lutea* (indispensable), *Nepeta Mussinii* and the richer-coloured *N. violacea*, *Cistuses* and *Helianthemums* may be relied on to give a good show also. These, although adding considerably to "K. L. D.'s" list, by no means exhaust the autumn bloomers, which are being added to every week and will be in the future; and though we may never equal the spring display on the rock garden, I think sufficient material is in evidence to prove that, apart from the great interest that is always present to the true rock gardener—whether his plants are in bloom or not—there is now no need to fear any dull season (except the depths of winter) on the rock garden.—ALVA J. HALL, *Harrogate*.

NOTES ON CARNATIONS.

HOW apparently indifferent details affect results was brought home in a forceful manner in the way two batches of cuttings rooted, the later batch, inserted and treated in every way similarly to a batch put in eight or ten days earlier, being the first rooted. The one difference consisted in the later batch being thrown into water as the cuttings were detached, and in the earlier batch being kept in a dry state till prepared, and then inserted in sand and water. There was no evidence to the eye of any difference in the cuttings all along; but that the slight drying was followed by the best results cannot be doubted. Lots of plants can be grown without being so particular about slight details; but, depend upon it, the Perpetual-flowering *Carnation* is not one of these, and much of the ultimate success or its opposite is the result of attention to seemingly trivial things at an early stage of their existence as plants.

Such another I would like to emphasise at this time. It is that the young plants, once root action is set going after the newly rooted cuttings are potted, should be grown coolly and as well ventilated as the weather permits. It is true the growth will be less rapid up to March or April, and the progress made by those which have been subjected to a more generous, if less bracing, treatment will be more in evidence. But day by day—afterwards the hardier brought-up youngsters will shoot ahead, and before long leave their pampered competitors in the rear.

For Flowering Plants the most exacting period of the year has now been reached. There are several things to be guarded against—insect infestation for one, and frequent vaporising must take place as a preventive rather than a destructive measure. Slight heat in the pipes is advisable, because it permits of the maximum of ventilation without reducing the temperature below that needed to keep the plants moving, though ever so slowly. Overheating and lack of ventilation are, however, disastrous. Manuring and watering are also of prime importance. If manure has been recently applied, no more should be needed till well on in January. At this season it has a very decided effect on the calyces and on the quality of the petals, but in neither case a beneficial effect.

The Application of Water depends to some extent on the quality of the soil, some soils retaining moisture much longer than others. At the same time, it must have been patent to all who have grown the *Carnation* with observation that it is a plant that succeeds best when it is not necessary to apply water frequently. I should be inclined rather to lower the temperature a few degrees during the winter months, so as to reduce at the same time the quantity of water, than to be more often called to moisten the soil. At the present time, plants in proper condition should be furnished with buds in all stages, and it is absolutely certain that a little veering to overheating, overmanuring and overwatering for the next six or seven weeks will weaken the plants permanently and depreciate the spring supply of bloom. Still there are occasions when it is more important not to conform strictly to what one knows to be the correct treatment than to go on these lines; such, for instance, when an abundance of bloom is required for some special purpose.

A week or so of a higher temperature may then, and should be, risked, and the plants as a rule will not suffer appreciably.

Border Varieties from Cuttings.—I have not previously noted how satisfactorily some border *Carnations* can be increased by means of cuttings taken at this time. The cuttings should be selected from the stems, these invariably rooting best. They may be inserted in sandy soil under bell-glasses or in frames and kept close till rooted; but by far the most satisfactory way is to treat the cuttings in the same manner as Perpetuals. They root in about the same time, and if potted promptly and in due time transferred to a cold frame or pit are capital material for planting out in the spring before the cold-treated cuttings have scarcely rooted. These have the advantage of layers—in Scotland at least—in flowering later. Let me add that potted layers being wintered in frames should be kept perfectly dry. The lights need not be put over them in fine weather; in wet certainly, but with the maximum of ventilation. No frost nor *Carnation* malady will affect them under these conditions.

R. P. BROTHERSTON.

APPLES AND PEARS: THEIR FLAVOUR AND PEDIGREE.

THE eating of a fine ripe fruit of the Mother Apple (the American Mother of most catalogues) has set me thinking on the value and importance of flavour in our modern fruits, and, incidentally, on the interest which attaches to their pedigree and origin. On referring to the admirable list that Mr. Edward Bunyard has compiled on the origin of our present-day Apples, I find "Mother (American), origin uncertain," and it is the same monotonous story with the very large proportion of the things we devour and enjoy. I had a letter from a horticultural friend recently, deploring the lack of any record of some of the best-flavoured Apples now popular. He wrote: "All our best fruits came to us haphazard, no one knows how," and he goes on to extol and encourage the practice of "considered crossing, on definite lines"; and to anyone who proceeds in this way added interest and value will be given—to the horticulturist, at any rate—if detailed records are kept.

If anyone asked me what motive to work for, I should reply, "Flavour, flavour, and again flavour." There is an enormous quantity of fruit "chucked" on to our markets that will appease the appetite of a hungry man; but to the man who possesses a brain and a palate (and the two generally go together) what a small selection there is! Among Apples we have Cox's Orange Pippin, *facile princeps* in a good season. Let us see what Mr. Bunyard has to tell us of this fruit, "raised by Mr. Cox of Slough and introduced about 1850"; again no pedigree. Then we have Mother, mentioned before; Cornish Gilliflower, superbly flavoured when in perfection, but just a foundling like the others.

The series of Apples raised by Mr. Charles Ross do indeed possess a pedigree, and very handsome fruits some of them are; but I have tried hard, and I regret to say unsuccessfully, to find any trace of so fine a flavour in them as is possessed by any one of the trio that I have named above.

In fact, I think that Mr. Ross appears to have worked generally on quite wrong lines in choosing for one of the parents of most of his hybrids such a huge and particularly uninteresting fruit as Peasgood's Nonsuch. I believe that Messrs. Laxton, and probably several others, are at work on the lines that I have indicated are desirable; but I do not think that they have as yet put any particularly superb variety into commerce.

Let us turn to Pears. My two especial favourites are Seckle and, of course, Doyenné du Comice. To paraphrase Shakespeare, the man who does not appreciate a fruit of Doyenné du Comice is indeed "fit for treasons, stratagems and spoils." When at its best I confess I do not know of anything in the world that is more delicious to eat. Mr. Bunyard says that it was "raised by the Horticultural Society of Maine et Loire at their garden in Angers, France, and first fruited in 1849." The fact that the Horticultural Society of Maine et Loire has not apparently seen fit to publish its pedigree

people do; and not long ago a letter came my way from a still young man who was retiring from Parliament asking my advice as to what particular branch to take up in the hybridisation of plants. I advised him to "go for the Apple." I hope he is now doing so. Although I have dabbled in the cross-breeding of various plants and have put in a good deal of earnest work with some things, notably flowering bulbs, fruits have not up till now been within my line; but should I at any future time have the opportunity, I do not think I should fail to keep and maintain as complete a record of the pedigrees as it would be possible for me to do, always bearing in mind of what immense importance and interest such a record would be to many others besides myself.

F. HERBERT CHAPMAN.

[We have considerable pleasure in publishing Mr. Chapman's article, as it deals with a subject that is of peculiar interest and importance to gardeners and fruit-growers. Unfortunately, the

GOOD VARIEGATED PLANTS FOR THE HARDY BORDER.

AMID the wealth of flowering subjects for the hardy flower border, the claims of foliage plants are apt to be overlooked. I purpose, therefore, to briefly draw attention to a few of these whose beauty lies in their variegation. I begin with *Iris Pseudacorus* fol. var., the variegated Bastard Iris. In Scotland this beautifully variegated Iris begins to show up in the beginning of May and keeps good for six weeks or two months, after which it begins to lose its brightness. About the afore-mentioned date *Funkia undulata* fol. var., the variegated Wavy Funkia, unfolds its beauty, both in colour and form. The variegation of both the foregoing is of a pale primrose shade. *Symphytum officinale* luteo-marginata, being a Comfrey, may be regarded by some as being rather coarse, but its golden-margined foliage justifies its inclusion in any collection. It should be planted near the front of the border, and the flower-stems ought to be cut over as soon as they begin to appear.

In *Hemerocallis Kwanso* var. we have a plant with gracefully recurving foliage, and with a lovely silver variegation suggestive of a small specimen of *Pandanus Veitchii*, but as easily grown as any of the other Day Lilies. *Phlox Comtesse de Jarnac*, being of more recent introduction than any of the preceding, is on that account better known, but it well deserves the popularity it enjoys. Planted in groups of threes or fives, it has a very telling effect.

Scrophularia nodosa var., the variegated Murrain Grass, was a popular bedding plant in the sixties and seventies of last century, but, like many of its contemporaries, it has long ago been relegated to the limbo of forgetfulness. Its merits as a silver-variegated plant, however, entitle it to a place in the hardy border, which it always enjoys here. The flower-stems should be pinched out as soon as they begin to push. The variegated

Balm, *Melissa officinalis* var., is well worth attention, and can be either allowed to develop or be pinched back and used for the front lines; it shows up best in poor soil. Of the dwarfer variegated plants I will only indicate a few. *Dactylis glomerata* var., the variegated Cocksfoot Grass, is another of the old popular bedders and has never been quite discarded; its form and colour both entitle it to a place in the hardy border. *Arabis albida* var. is very well known and is frequently used for edging walks. It is of *A. lucida* var. I desire to speak, however, with its rosettes of golden-variegated shiny foliage hugging the ground; truly a gem of the finest quality. Some people have difficulty in getting this plant to thrive, but its culture is simple. Prepare the ground well prior to planting, working in some good flaky leaf-mould; plant deeply, move seldom, but prick round the plants each spring with the hand fork, and, slightly lifting the foliage, top-dress with a little fresh loam

FRUITING BRANCH OF CHERRY KENTISH BIGARREAU. TREES MAY BE PLANTED NOW.

does not deter me from raising my hat to our good Ally, La Belle France, as I have done many times recently.

Seckle is a little fruit of beautiful melting flavour, of American origin, "found in a wood near Philadelphia," and that is about all we know respecting it. It apparently never had a father and a mother, but, like Topsy, just "grewed." Any evidence of hybridity in all these things, any trace even of the seed-parent, is missing.

I have read somewhere that the late Mr. Rivers, after tasting an Apple or Pear that he found of good flavour, would save the pips and sow them in pots which he had duly filled and prepared ready to hand, an old-fashioned method which had its merits, as a record of the seed-parent could then, of course, be kept; but the present-day seedling raiser is, I hope, raising his things on far more methodical and up-to-date lines as a rule. I look upon the Apple as far and away the most valuable of all our fruits. I imagine that most

process of raising new Apples, Pears and many other fruits on systematic lines is a very slow one, and many nurserymen cannot afford to devote the necessary time to it. We think it is a subject that the scientific and research establishments now subsidised by Government or other public bodies might profitably take up.

A GOOD SWEET CHERRY.

ONE so often hears complaints that Cherries do not crop well in gardens when grown as bush or half-standard trees. Undoubtedly a wall is desirable for most of the choicer kinds, but the variety illustrated herewith, and named Kentish Bigarreau or Amber Heart, will do well in most gardens grown in either of the forms named. It is a very old variety, with fruits of medium size, pale yellow in colour, with red on the exposed side. The flesh is white, juicy and sweet, and the fruits are in season during July. FRUIT-GROWER.

and flaky leaf-mould; pick off the flowers as soon as they begin to appear. *Thymus citriodorus argenteus*, the silver-variegated Lemon Thyme, is suitable for front lines: moreover, it is as acceptable to the cook as is the type. The variegated form of London Pride (*Saxifraga umbrosa*) is very attractive, but requires to be selected from time to time, as it inclines to revert to the type.

Midlothian.

CHARLES COMFORT.

ROSES IN YORKSHIRE.

(Continued from page 588.)

IN continuance of the vigorous red varieties, I come to

George Dickson.—Here is a Rose that takes one by storm. I shall not easily forget the impression I received when first I saw it staged in masses of gorgeous blooms by the raisers (Messrs. Alex. Dickson and Sons). I returned again and again during the afternoon to examine this fine Rose and to feast my eyes on its lovely colour. It was without doubt the magnet of the show, and before I left I had both ordered the plant for the autumn and managed to possess myself of a spare bloom, which, by the way, lasted considerably more than a week in water. It is truly described as the finest dark red Rose in cultivation, with its glistening blackish crimson petals of great substance. It is an acquisition to any garden, and now available at a more popular price, which is bound to add large numbers to its many admirers. With me this Rose has grown well, and produced blooms which, if few in number, have been of high quality. Perhaps its one fault is a tendency to hang its head. The blooms are heavy, and the stems not quite as firm and vigorous as one would like; but, apart from H. V. Machin (at present beyond my pocket), I have seen nothing to rival it, and I am quite satisfied with the results in the climate of my garden.

George C. Waud also does well here, and is specially attractive because of its unique colour, almost a vermilion, which has the added charm of being able to endure the sun. I have yet to see a bloom that has lost its colour on the tree. It is now threatened with rivalry by *Geoffrey Henslow*, a variety which is obviously a more vigorous grower, but one with which I have had as yet very little experience. I have planted more of it this autumn. Other reds that are reliable in this district, but which I have only space to name, are

General Macarthur, with me specially good in the autumn

Edward Mawley.—Excellent, erect habit of

Alfred Colomb and **Captain Hayward.**—The latter is of a rather thin nature; opens well here even in cool, damp weather.

The varieties of pink and salmon colours are so numerous that it is a work of art to select those that one can usefully grow in a garden which, though somewhat limited in size, is required to contain the best varieties of all colours. In the pure shades of china pink I give pride of place to

Mrs. George Shawyer.—Its habit of growth is free, it is very shapely in the bush, while it produces fine blooms carried on long, stout stems. Another Rose of this lovely soft shade of pink is

Berthe Gaulis.—Unfortunately, it is very moderate in growth here, and while producing

use for exhibition purposes with success, but believe its vocation is mainly a decorative garden Rose.

Caroline Testout.—A very vigorous Rose, and even here continually in flower. It comes unscathed through severe frost and biting winds that play havoc with bushes all around it. For this reason alone every exposed garden should contain it.

Baroness Rothschild is also a very robust Rose, giving perfect blooms of satiny pink and of fine cupped form. The disappointment comes when we are seeking fragrance, a quality which, as every rosarian knows, it is guiltless of

Mme. Abel Chatenay.—One of the indispensable varieties with me. The three or four

plants I have of this variety have given me literally scores of blooms, all borne on long stems, so that they can be cut without the sacrifice of buds. It is a pity it is not a more shapely grower, as it is undoubtedly reliable in every other direction and one we cannot do without.

The Lyon.—It seems invidious and almost unnecessary to write about this variety, with its unique colour of shrimp pink, shaded chrome yellow. In spite of its ungainly growth and its extreme variableness in colour, it is excellent. I have nicknamed it Chameleon, but from it I have cut certainly the largest, and some of them the finest, blooms in my garden. Even on November 22 I managed to find quite a respectable bloom fit for the vase. Out of some seventy varieties I am growing at present, only five have shown any sign of mildew. Unfortunately, *The Lyon* is one of them, although perhaps the least affected of the lot. The worst offender in this respect is *Killarney*, which I have this year expelled from the garden. In my humble opinion it is not worth its room, as it remains mildew ridden against all treatment.

Prince de Bulgarie.—Pale flesh, with rosy salmon centre and attractive shell-shaped petals, this is undoubtedly not only a robust variety, but may be safely classed among town Roses. It has flowered with me continually and right on into late autumn.

Roundhay, near Leeds. E. WATERS
(To be continued.)

THE GLOBE THISTLES.

These interesting hardy plants, known to botanists as *Echinops*, are particularly valuable for grouping in the mixed border, where their globular flower-heads of steely blue add a touch of colour such as we get from few other kinds. They are not at all difficult to grow, flourishing in ordinary garden soil that is well drained and manured. Those who are planting borders now should certainly find room for one or two groups of these Globe Thistles. The best kinds are *E. ruthenicus*, *E. altissimus*, *E. ritro* and *E. banaticus*. I

A FINE PLANT OF THE GLOBE THISTLE, *ECHINOPS SPHAEROCEPHALUS*. THE FLOWER-HEADS ARE STEELY BLUE.

perfect blooms, seems unable to support them. Possibly *Dean Hole's*—or is it *Mr. Mawley's*?—theory of the mowing-machine over the amateur's beds at pruning-time might help me with this variety.

Mrs. John Laing is, of course, a good doer here, and gives numbers of blooms, but one has to make up one's mind early whether three or four exhibition Roses or a decorative bush is required. Quality and quantity are foreign to this Rose. I prefer the quantity, as there are others for exhibition if wanted in this colour.

Lady Ashtown.—Another beautiful pink that is exceedingly floriferous and a decided acquisition to the garden. I have grown it well enough to

AUBRIETIAS IN THE SPRING GARDEN.

THOSE who make careful use of the best spring flowers have been rejoicing in some recent improvements in the Aubrietia. Among these, the most valuable of those now well known is the beautiful variety Lavender, of good size, fully bloomed and of true Aubrietia colour. In the progress of variation of a garden plant, growers are apt to overlook the best purpose or intention. The figures of size, novelty and variety are often illusive; they attract and lead into blind paths. The thing to look for is the purest beauty of which the plant is capable. In the matter of colouring in the Aubrietia the very finest quality may often be picked out in a batch of seedlings of the type *A. græca*. It is a clear, pure lavender purple rather light than deep in tone. We are grateful for the fine deep-coloured variety Dr. Mules, but to the artist-gardener it is not a plant to use by itself in large quantity. Its value is best shown when a few plants are grouped with a larger number of a good form of the more typical colouring. Of the heavy reddish colourings, and even the deep purples inclining to reddish, as far as my own feeling and experience are concerned, they are better avoided altogether. The only colourings with anything approaching a reddish tint that seem to me desirable are the very beautiful palest pink *Moerheimii*, of Dutch origin, and a slightly darker one, brought out, I think, by Messrs. Barr, called Bridesmaid. Both are extremely pretty plants and go well together. For the present the pure, rather light-coloured kinds resembling the fine Lavender would seem to be the best. It was a pleasure last spring to receive from Mr. R. Wallace of Colchester a very beautiful flower of the Lavender type, but better, in that it had not so much of the pale eye that in Lavender is rather too conspicuous. The absence of the white eye makes the flower much more effective in the mass. I am of opinion that the size of Aubrietia bloom should not be further increased. Aubrietia the size of Rocket or Honesty would be a disquieting anomaly. It is not in the nature of the plant, a true alpine, to have large flowers. The mass of small blooms of good form and pure colouring is the true character of the plant and the source of its charm and attractiveness. These charming spring flowers deserve to be more widely grown, both in the rock garden and the border, than they are at present. Their cultivation is not difficult, and they are ideal for the amateur.

G. JEKILL.

THE MOST BEAUTIFUL CLEMATISES.

ONE of the most beautiful families of shrubby and climbing plants is the Clematis. Those who have only a slight acquaintance with flowers know the Traveller's Joy (*Clematis Vitalba*), the misty seed-pods which give a weird effect to the hedgerow in autumn and winter. It rambles over everything within its reach, mingling its silvery colour with the dense glossy green of the Ivy. It is not of the wild Clematis one wishes to write, but the following question

note as to the time they flower and the colouring. All thrive best in a cool soil, such as loam with some lime in it, and in the case of *Clematis Jackmanii*, *C. lanuginosa* and their varieties the bases of the plants should be in such a position that the full rays of the sun do not strike directly upon them during the hottest part of the day.

THE SPECIES OF CLEMATIS.

The following are a few of the more beautiful of the species or wild types: *C. alpina*, which flowers in April and May, is a Clematis from Northern Europe, and bears lilac or mauve blooms in abundance; there are varieties with

white and pink flowers respectively. *C. campaniflora*, a Portuguese Clematis, with white, mauve-tinted flowers barely one inch across, is of strong growth and suitable for the wild garden; the flowering period is from July onwards. *C. Flammula* is well known; its fragrant white flowers, which appear in August, are familiar. The charming variety *rubro-marginata* has flowers margined with red. *C. florida*, a native of Japan, is the parent of one of the types of Clematis which give beauty to the English garden; these bloom in May and June and must not be pruned in spring. *C. lanuginosa* is the parent of many of the largest-flowered garden varieties which bloom from July onwards; all the varieties of this type require to be pruned fairly hard in February. *C. montana* is one of the most beautiful climbers we possess. Its glistening white flowers cover the leaves with their beauty during May and June. A lovely form of it is called *rubens*, which has reddish flowers. *C. orientalis* is easily recognised by its small yellow flowers, which appear in August; it is, however, less beautiful than the variety called *tangutica*, which has larger flowers of richer colour, and these appear from July onwards. *C. patens* is another Clematis from which many garden varieties have been obtained. The forms of this have white or blue flowers in June; the species is found both in China and Japan.

C. Viticella produces many garden varieties, while it is one of the parents of the well-known *C. Jackmanii*. The growth is strong, and the purple flowers appear in profusion.

SELECTION OF VARIETIES.

***C. florida* Varieties.**—These all flower in May and June from buds on the wood matured the previous year. Belle of Woking, silver grey, double; Comète, white, with mauve stamens; Countess of Lovelace, mauve, double; Duchess of Edinburgh, white, double; Elaine, blue, double; John Gould Veitch, lavender, double.

A SINGLE PLANT OF AUBRIETIA IN THE ROCK GARDEN.
DIVIDED PORTIONS MAY BE PLANTED NOW.

has suggested notes upon this beautiful group of flowers: "Would you be so kind as to give me the names of what you consider to be the best hardy, free-flowering Clematises; colour, deep blue, mauve, lavender, and white, none with bars or bands upon them? They are for planting against a wall, but in rather an exposed position, so that I wish them to be hardy and to be at their best during June and July."

In reply to this the following lists have been carefully compiled. Species—that is, wild kinds—have been enumerated and also the varieties, with a

Lucy Lemoine, white, double; Proteus, rose purple; Undine, blue, double.

C. patens Varieties.—These varieties, like the foregoing, blossom from wood matured the previous year; consequently no pruning must be done in spring. Albertine, white, semi-double; Albert Victor, deep lavender, with pale bars; Edith Jackman, white, flushed mauve; Fair Rosamond, blush white, with red bars; Lady Londesborough, silver grey, pale bars; Lord Londesborough, mauve; Miss Bateman, white, red anthers; Mrs. Quilter, white; Sir Garnet Wolseley, pale blue, with reddish bars; Standishii, lavender blue; The Queen, pale lavender; Uranus, blue.

lavender, with violet bars; Princess of Wales, deep bluish mauve; Ville de Paris, white, tinged lilac.

C. Jackmanii Varieties.—All the varieties belonging to this group flower on young wood, and are improved by being cut back to within a bud or two of the base of the previous year's wood in spring. They blossom from August onwards. Alexandra, reddish violet; Earl of Beaconsfield, purple; Gipsy Queen, purple; Jackmanii superba, rich purple; Jackmanii alba, white; Jackmanii rubra, red; lilacina floribunda, grey lilac; Mme. Edouard André, red; magnifica, reddish purple; Rubella, purple; Snow White, white; Star of India, purple, red bars; Ville de Lyon, red.

PLANTING IVY UNDER LARGE TREES.

In a good many private gardens and public parks the ground beneath large trees is bare and unattractive, owing mainly to the fact that grass will not grow, especially where the tree is a dense-growing kind. Such bare places are, to say the least, an eyesore, and an unnecessary one at that. Although there are a number of plants that will grow in such positions, it is doubtful if any are better than the common Ivy. This will thrive in almost any kind of soil, keeps green all the year round, and beyond an annual cutting over in spring needs little attention. In the accompanying illus-

A GARDEN SCENE SHOWING A LARGE TREE WITH AN UNDER-PLANTING OF IVY.

C. lanuginosa Varieties.—These varieties commence to flower in July and continue for a couple of months. The branches may be pruned fairly hard in spring, say, to within four or five buds of the base of the previous year's wood. Alba magna, white; Beauty of Worcester, bluish violet; Duke of Norfolk, deep mauve, with broad, pale bars; Fairy Queen, pale flesh, with pink bars; Gem, deep lavender; Grand Duchess, white, flushed rose; Lady Caroline Nevill, blush white, mauve bars; La France, violet purple; Lord Nevill, blue; La Gaule, white, semi-double; Louis van Houtte, violet purple; Mme. van Houtte, white; Marcel Moser, pale

C. Viticella Varieties.—All these blossom on young wood from July onwards. The branches may be cut fairly hard back in spring. Ascotensis, blue; kermesiana, red; La Nancienne, violet, double; Othello, purple; rubra grandiflora, red; Othello, white and purple. Clematis Durandii is a very pretty, bluish-flowered hybrid which is said to contain C. integrifolia blood. It is of good constitution, and blossoms very freely from July onwards. There is a paler variety called pallida. The foregoing lists, though extensive, could be added to, but sufficient have been named to enable anyone to make selections ample enough for any ordinary sized garden.

tration the effect of Ivy growing under a tree such as we have in mind is well shown. The present is a good season for planting. The soil should, however, be first dug over at least a spit deep, and if a few roots are damaged in the process, no appreciable harm will be done. If it is very poor, it will be improved by the addition of old potting soil, mud from ponds or ditches, or, indeed, almost anything that contains plant food. Small pieces of Ivy with roots attached are easily procurable, and may be planted from 1 foot to 18 inches apart. Of course, the Ivy will not be allowed to climb the trunk of the tree; if cut over annually, there will be no danger of this.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Cherries.—The earliest batch of trees should now be placed under cover, especially if ripe fruits are desired in April. Little more than protection will be necessary for some time, as the Cherry will not stand much heat until the stoning period is over. A temperature of 40° at night is quite high enough for the next two months, and this may be allowed to drop to 35° if sharp frost sets in, merely allowing sufficient heat in the pipes to exclude frost. Open the ventilators freely during mild weather, and syringe the trees about midday when the weather is bright. Very careful attention is necessary in regard to watering.

Protecting Vine Borders.—Although the roots of early Vines should be indoors, there are instances where this is not the case, and it becomes necessary to protect the roots from cold rain and snow. For this purpose some light, warm material should be provided, such as Oak leaves with a small quantity of stable manure. The leaves produce a mild and lasting heat which is all that is necessary, and this material should be covered with corrugated zinc to carry off the moisture.

Late Vine Borders containing Vines on which the Grapes are expected to hang for some time yet should be covered with dry leaves and shutters of some kind to cast off the rain. This is better than placing a quantity of manure over the borders in winter.

Cucumber Seeds should be sown now, and treated in the same way as advised for Melons in last week's calendar. The plants should be ready to put out in January.

Plants Under Glass.

Gardenias.—Plants in pots will need to be watered carefully at this season. Admit fresh air to the house whenever external conditions permit, as nothing is more detrimental to these plants than a close, stagnant atmosphere. Those which are planted in the border must be protected by some covering material if cold weather sets in. This is better than an increase of fire-heat.

Mignonette.—If seeds were sown in small pots in September, the plants will now be ready for potting into larger pots, and this should be accomplished at once, or the colour of the foliage will suffer seriously. Good fibrous loam and decayed manure will suit them well, and a good sprinkling of old lime rubble may be mixed with the compost. Pot firmly, and place the plants in a cool, light position.

Lachenalias.—These plants should now be removed from the cold pits to a position near the glass, in a temperature of 45° by night. When the pots are well filled with roots, manure-water may be applied in a weak state, and, as time advances, a few of the most forward plants may be removed to warmer quarters in order to prolong the flowering season.

The Flower Garden.

Climbing Roses.—The supports to all climbing Roses should be examined now, and all repairs or renewals made before the plants are tied into position. In thinning the plants, as much of the old worn-out wood should be removed as can be spared, as by far the best display is produced from young, healthy wood. In all cases the branches ought to be allowed sufficient space between them to ensure the full development of the flowers and foliage during the summer. In cases where new plants are necessary, the ground should be deeply trenched, and enriched by a quantity of decayed manure from the farmyard.

Berried Shrubs.—If sharp frost sets in, some protection must be provided to berried plants, or the birds are almost sure to work havoc among them. This is easily avoided by placing ordinary garden nets over the plants at once, and, in the case of Mistletoe berries, the nets should be secured round the best bunches without delay.

Garden Paths.—The present is the best time to make or renovate garden paths. In all cases drainage should be the first consideration; for if this is not sufficient, the surface of the paths is sure to present a sodden appearance during the

winter months. If new paths are to be made, the ground should be removed to the depth of 15 inches, especially if there is considerable traffic, and the bottom filled up with good hard core to within 6 inches of the surface, finishing off with the best gravel available. Old walks may be forked over, and if the gravel has lost its colour, a dressing of new material should be applied.

Hardy Fruit.

The Fruit-Room.—Frequent attention will be necessary in order to keep the room quite free from decaying specimens, which must be removed as soon as noticed. Sound fruits are best left unmoved, especially in the case of Pears which are approaching ripeness. Keep the ventilators open in order to allow the atmosphere to be as dry and cool as possible.

The Kitchen Garden.

Chicory.—The forcing of this winter salad plant should receive attention. It is a very easy matter to keep up a supply of tender young leaves throughout the winter, provided some dark, warm chamber is available for the purpose. If only a small supply is necessary, it may be grown in pots in the same way as Seakale. The crowns should be a little above the soil, as the young leaves are easily affected by dampness.

Lettuce and Endive in frames must be freely ventilated during mild weather. Stir the soil between the plants and remove all decaying foliage. The aim should be to keep the atmosphere of the pit as dry as possible during the winter.

Carrots in Frames.—Young Carrots are always welcome, and to have them ready in April the seeds should be sown in a gentle hot-bed about the end of the year. A brick pit without fire-heat will suit them well, and if a bed of leaves can be made up now, there need be no difficulty in producing a satisfactory crop. Protection from frost may be provided by placing mats or dry Bracken over the lights as it becomes necessary.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Mushrooms.—Beds that have been in bearing for a time and are showing signs of exhaustion should be given a thorough soaking of liquid manure with the chill taken off. In collecting material for making up fresh beds, the manure should be spread out in a shed with an open front and turned over regularly every day, as it is sometimes no easy matter to get it sufficiently dry at this season of the year. The temperature in the Mushroom-house should not fluctuate very much; endeavour to maintain it at from 50° to 55°, and keep the atmosphere moist by syringing the walls and paths.

Early Carrots.—If a sowing of Carrots in frames has not been made to provide a supply early in the new year, this should be seen to at once. It will be necessary to place the frame on some hot-bed material, and also to put some of this round the sides. As mentioned in a previous calendar, nice little Carrots can be had when grown in sand with the addition of a little wood-ashes if this is procurable. Beyond correct ventilation—and this must be given on fine days—they require little attention.

Rhubarb.—A few more roots should be lifted to be in readiness for placing in the forcing-house, and to keep up a succession a number of crowns should be covered either with Rhubarb pots or ordinary barrels. It will usually be found that the quality of the Rhubarb is much finer when grown in this way.

The Flower Garden.

Christmas Roses.—In order to have these in bloom towards the end of the month or the beginning of January, it will be necessary to place hand-lights or frames over them now that the flowers will be showing. By this means the flowers will be very much purer and fresher. To increase the flower-stems, the plants should be given frequent applications of liquid manure in a tepid state.

The Rockery.—Now that the leaves of all deciduous trees will have fallen, the rockery ought to be gone over, and all leaves that are lodging about the plants should be removed. It has been advanced by many that these leaves act as a sort of protection to rock plants. This may be true in some districts, but it certainly cannot be so in the Northern Counties, where we are subject to so much moisture during winter. As I have frequently pointed out, a far better protection is to be found in placing some grit or chips of slate or granite round the necks of the plants, which will not only keep the latter safe from moisture, but will also ward off slugs.

Ceanothus Gloire de Versailles.—Among autumn-flowering plants it is doubtful if this Ceanothus has an equal. It blooms profusely, and the delicate blue or lavender flowers are always greatly admired. Where these are growing against a south wall, no protection should be necessary, but in more exposed positions a little protection must be given. It may be added that the growths should be well cut back in the spring, as the flowers appear on the young growths.

Plants Under Glass.

Mignonette.—The most forward plants that have been grown on in pots for early spring flowering ought now to be staked, as it is important that they be kept in an upright position. In order to secure good heads, all the side growths should be removed, and, as the pots become filled with roots, the plants may be assisted with some weak liquid manure. They should be grown as close to the glass as is consistent with safety.

Coleus thyrsoides.—As these plants are fast developing their flowers, they must be given more room, and on no account should they be subjected to excessive heat. A greenhouse temperature will suit them admirably at this stage, and they should be well exposed to the light.

Cyclamens.—A number of the most forward plants may be introduced into a little more heat to give an early supply of flowers. There is always a danger of these plants being attacked by thrip when grown in a dry atmosphere, so that every means should be taken to prevent this by occasional fumigation. When they come into bloom they should be removed to the greenhouse.

Nephrolepis.—Perhaps there is no class of Ferns more handsome and none more suited for furnishing stands in the public rooms or more attractive in the conservatory than the various forms of this Fern. To mention but two varieties—*Piersonii* and *Whitmanii*—it would be difficult to find more elegant Ferns when well grown. These can be propagated by pegging down the small offsets into a bed of fibre, where they will quickly become established.

Violets.—This is perhaps the most critical season for the successful cultivation of the Violet under glass, as during the short, dull days of December it is difficult to keep the plants from damping. Under ordinary circumstances little or no water will be required, but, should it be necessary, care must be taken not to wet the foliage when watering.

The Hardy Fruit Garden.

Canker in Apple Trees.—Various causes are attributed to the presence of canker in these trees, but possibly the chief is the roots getting into an unsuitable subsoil. Where it is not possible to lift and replant affected trees, much can be done by carefully paring the diseased part and painting it over with coal-tar. Give the ground round the trees a good dressing of hot lime.

Fruit Under Glass.

Strawberries.—Where Strawberries are expected early in the season, a batch should now be placed in a house where a slight heat can be maintained. The plants ought previously to have the loose soil removed from the pots and be top-dressed with a mixture of good loam and a little artificial plant food, and afterwards be arranged on a shelf close to the glass. As they commence to grow, a little more heat should be turned on, and the plants lightly sprayed over on fine days. In the earlier stages of growth water must be applied with care, as failure will result if the soil becomes sodden.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

GARDENS OF TO-DAY.

BRANSFORD HOUSE,
CHRISTCHURCH.

THIS, the charming residence of Major and Mrs. Wyndham Pain, is situated on the high wooded slopes bordering the New Forest to the north-east of Christchurch, and commands magnificent views of the sea and landscape for many miles, ranging from south-east to west. Immediately below the broad terrace in front of the mansion there is a rockery border well furnished with suitable kinds of plants, grown in masses, with good effect. *Romneya Coulteri* thrives remarkably well in a warm corner of this border, and bears flowers of extra large size. The terrace itself opens on a square-shaped formal garden, well enclosed, on the south side. Here in summer and autumn Ivy-leaved *Pelargoniums* Charles Turner and Mme. Crousse show to great advantage. *Heliotrope* Lord Roberts, *Pentstemon* Phryne, *P. Pink Bedder*, *P. Southcote Gem*, *Pansy* Lord Beaconsfield, purple *Petunias*, *Lobelia Victoria*, *L. Carmine Gem*, *Antirrhinums*, *Nicotianas* and Scented leaved *Geraniums* combine to make a fine floral display even as late in the season as October.

The front lawns are enclosed by Yew hedges, and the long, formal borders here, which are in keeping with their immediate surroundings, contain fine collections of Michaelmas Daisies. They formed a unique feature, and showed to much advantage against their dense background of Pine trees. A long and broad sweep of lawn, bordered by Pines and Furze (which grows remarkably well in this district), leads gently downwards to the south-west to the Rose garden, which opens suddenly to the visitor, and comes as a most pleasant surprise, as the numerous beds are formed on both sides in floral recesses. This is a fitting termination to the grass glade, with the mansion at the head.

Mr. P. C. Kitcher, the able head-gardener, has splendid crops in the vegetable and fruit gardens, as well as of plants under glass. Zonal *Pelargoniums* fill one span-roofed structure. The plants were grown in open air during the summer, and are now bushy specimens, flowering freely. Notable are Lady Warwick, Mary Carmichael, Prince of Wales, Princess of Wales, Stella Massey, Snowstorm, Mark Twain, Mme. Friedlander and Mrs. Lawrence, among some thirty odd varieties. *Chrysanthemums*, both for the production of large blooms and in sprays for decoration, are grown to perfection. Very fine were Miss Elsie Davies, Reginald Vallis, Queen Mary, His Majesty, Kara Dow, Mrs. Gilbert Drabble, W. Turner, Pockett's Crimson, George Hemming and Bob Pulling. One ideal span-roofed house was filled with remarkably healthy Tree Carnations.

There are many other lovely features which space forbids recounting, but I wish to express my gratitude to Major and Mrs. Wyndham Pain, who take such keen interest in their beautiful gardens, for kindly permitting me to inspect them.

G. GARNER.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Chrysanthemum Mollie Godfrey.—A single-flowered variety of large exhibition size, and of that precise tone of cerise pink which, modified

THE NEW BRASSO-CATTELEYA SHOWN BY MESSRS. STUART LOW AND CO. IN LONDON LAST WEEK.

or refined when seen under artificial light, is of inestimable value to the florist-decorator and generally for decorative work. From E. Mocatta Esq., Woburn Place, Addlestone (gardener, Mr. T. Stevenson).

Brasso-Cattleya Pink Pearl (Cattleya Lord Rothschild x Brasso-Cattleya Veitchii).—An exquisitely beautiful variety of large size; sepal's, petals and lip wholly pink throughout, and of a very charming shade. Exhibited by Messrs Stuart Low and Co., Jarvisbrook, Sussex.

The above awards were made by the Royal Horticultural Society on the 1st inst.

CULTIVATION AND COLLECTION OF MEDICINAL PLANTS IN ENGLAND.

[The following has been recently published as Leaflet No. 288 by the Board of Agriculture.]

VALERIAN (*VALERIANA OFFICINALIS*, L.).

(Continued from page 591.)

Cultivation.—In Derbyshire cultivation is from wild plants collected in local woods and transplanted to the prepared land. Preference is given in collecting to daughter plants and young flowering plants which develop at the end of slender runners given off by the perennial rhizomes of the parent plant. Many of the young plants do not flower in the first year, but produce a luxuriant crop of leaves and yield rhizomes of good quality in the autumn. Planting is usually done on land treated with farmyard manure. Weeding requires considerable attention, and it is advantageous to give plenty of liquid manure and artificial fertiliser from time to time. The plants require plenty of water. Any flowering tops are cut off, as they appear, to encourage the growth of the rhizome as much as possible. In September or October the tops are cut off with a scythe and the rhizomes dry up. The clinging character of the Derbyshire soil does not allow them to be left later.

The rhizomes are sliced longitudinally to facilitate washing, which is done in a large perforated wooden box 2 feet to 2½ feet deep, secured by stakes in the bed of a local stream, a rake being used to stir up the "hearts." The rhizomes are dried on a shed floor about 6 feet from the ground. The wet material is strewn on perforated boards, below which a large coke stove is kept going until the drying is complete. About twenty-four parts of the dry product are obtained from 100 parts of fresh rhizome. Derbyshire Valerian plants are of two species, *V. Mickanii*, Syme, on limestone, and *V. sambucifolia* on the coal measures. The former yields most of the cultivated Derbyshire rhizomes.

OTHER MEDICINAL PLANTS.

Experimental growing of some American drugs, such as Senega

Grindelia, Pokeroor and Lobelia, is made at Darent. "Botanical herbs" for sale by chemists and medical herbalists are cultivated at Carshalton. They are grown in rows, which are increased in number according to the demand. The following are regularly cultivated:

Balm (*Melissa officinalis*, L.), for herb
Comfrey (*Symphytum officinale*, L.), for herb
Feverfew (*Chrysanthemum Parthenium*, L.), for herb
Greater Celandine (*Chelidonium majus*, L.), for herb
Germander (*Tenacium Scordonia*, L.), for herb

Marshmallow (*Althaea officinalis*, L.), for root and leaves.

Mugwort (*Artemisia vulgaris*, L.), for root.

Pennyroyal (*Mentha Pulegium*, L.), for herb.

Rue (*Ruta graveolens*, L.), for herb.

Southernwood (*Artemisia Abrotanum*), for herb.

Tansy (*Tanacetum vulgare*, L.), for herb.

Wormwood (*Artemisia Absinthium*, L.), for herb.

Yarrow (*Achillea Millefolium*, L.), for herb.

These herbs and roots are in steady demand, and although those grown in England are preferred, Continental supplies have to be imported to satisfy all needs. They are easily grown from seed, but propagation is commonly by division of old perennial plants. They succeed well from cuttings. Only Pennyroyal presents uncertainty as regards crop, this species being diminished by drought. Most of these crops are worth in the dry state from 20s. to 30s. per cwt.

(To be continued.)

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

ROSE GARDEN.

WEeping STANDARD ROSE DISEASED (J. B.).—The piece of bark sent is insufficient to permit us to say to what to ascribe the death of the weeping standard. We do not think it desirable to slit the bark of trees as a rule, and it may well be that the wound made admitted some fungus, which has brought about the death of the tree.

BUDDING ROSES IN SPRING (J. G. K.).—If by the spring you include May and early June, then our answer is, "Yes." You can bud stocks that were planted last year very well in May if you can procure ripe buds. Your best plan is to purchase young pot Roses of the newer sorts, which most Rose-growers have for sale in May, and these would give you six to ten buds each. When you speak of hard-wooded subjects being budded in the spring, we presume you really mean "grafted," and, of course, this is done in the month of March. While we would not say that Roses could not be grafted outdoors in a similar manner, yet we do not advocate its practice, as it is not at all a success.

SELECTION OF ROSES FOR A LARGE BED (Giles).—You will be able to make a splendid bed of Roses on the plot of land 39 feet by 8 feet. This would take four rows of bushes planted about two feet apart each way. In No. 1 row we have arranged all tall growers, and these, of course, would be placed at the back of the bed that is furthest away from the path. No. 2 row would be strong growers, but not quite so much so as No. 1 row; No. 3 row dwarfier than No. 2, and No. 4 quite dwarf. We have arranged them in the order they should be planted, commencing at the left end of the row each time. No. 1 row—Avoca, Mme. L. Constantine, Duke of Edinburgh, W. A. Richardson, Mrs. C. West, Sarah Bernhardt, La Tosca, Florence H. Veitch, Gustave Regis, Dr. O'Donel Browne, Ferniehurst, Margaret Dickson, Hugh Dickson, Bouquet d'Or, J. B. Clark, Lady Waterlow and Ulrich Brunner. No. 2 row—Mrs. Sharman Crawford, Laurent Carle, Betty, Lady Ursula, Gustav Grunerwald, Frau Karl Druschki, General Macarthur, Mme. A. Chatenay, François Coppee, Pharisier, President Vignet, Mrs. John laing, Captain Hayward, Lady Pirrie, Dorothy Page-Roberts, Charles Lefebvre, Caroline Testout and Mrs. H. Stevens. No. 3 row—Antoine Rivoire, Lady Hillingdon, Augustine Guinoisseau, Edward Mawley, Mme. Ravary, Lady Ashtown, Prince de Bulgarie, Mrs. A. Tate, James Coey, Richmond, Cissie Easlea, Lady A. Stanley, Joseph Hill, Duke of Wellington, Duchess of Wellington and Mme. Jules Grolez. No. 4 row—Melody, Mrs. W. C.

Miller, Entente Cordiale, Rose Queen, Chateau de Clos Vougeot, Paul Lédé, Amateur Teyssier, Victor Hugo, A. R. Goodwin, Mme. Segond Weber, George C. Waud, Marquise de Sinety, Mme. Antoine Mari, Fisher Holmes, Le Progrès, Lieutenant Chaure and Mrs. Aaron Ward. This would be a total of seventy plants. For the pillars we suggest the following: Effective, Climbing Mrs. Grant, Richmond, *American Pillar, *Leontine Gervaise, Zephyrine Drouhin and Elise Robichon. The two marked with an asterisk would come either side of the path opening. These are all popular Roses, with a good blending of colour and of easy culture. When planting, give each plant a handful of bone-flour just beneath the surface soil.

MISCELLANEOUS.

TREATMENT OF SOIL (H. A. Fordham).—We think your soil is probably somewhat sour and in need of lime. As you are going to take all the Carnations out, we think it would be advisable to put on a good dressing of lime now, using half a bushel of quicklime to each square rod, placing it in heaps and covering them with soil for about a fortnight, then spreading and digging it in. In addition to this, we should be inclined to give a dressing of sulphate of potash if you can obtain it in the spring, using 1½ oz. to the square yard. We do not think the millipedes will do very much harm to the woody roots of Roses, and would not use the lime there, but the sulphate of potash dressing alone. If your bush of La Tosca is still alive, though dormant, we would leave it to see if it will make new growth next spring. If all the wood is dead, dig it up and burn it. Of the Roses you name we can recommend the following for general garden use: Gustave Regis, Duchess of Wellington, Lyon, Mrs. David McKee, Lady Hillingdon, Mrs. Aaron Ward, Lady Alice Stanley and G. C. Waud. Other good varieties of comparatively recent introduction, but not now expensive, are Entente Cordiale (Pernet-Ducher's), Miss Cynthia Forde, General Macarthur, Arthur R. Goodwin, Lady Battersea, James Coey and Lady Pirrie.

VARIOUS QUESTIONS (Rustic).—"Color Standards and Color Nomenclature," by Robert Ridgway, published by the author in Washington, U.S.A., will give you the charts you desire. Clarkia is named after Captain Clarke, who accompanied Captain Lewis in his journey up the Missouri and to the Rocky Mountains in 1884. He flourished at the end of the eighteenth and the beginning of the nineteenth century. The name was given by Pursh, who, however, spelt it Clarcia. Pulchella means pretty or beautiful, and integripetala refers to undivided petals as opposed to those forms with the margins of the petals much cut up. Lupine is supposed to be derived from Lupus, the wolf, and was the name used for the plant by Virgil and Pliny. It is supposed to refer not to the form of the flower, but to the idea then prevalent that it devoured the fertility of the soil. Your derivation of the term Larkspur is probably correct. Shirley Poppies were first raised by the Rev. W. Wilks, the well-known secretary of the Royal Horticultural Society, from a single wild plant in his garden. He carefully "rogued" the seedlings year by year, and so established the beautiful race now in existence, and at the same time generously gave the seed to as many as asked for it. His garden was at Shirley Vicarage, Croydon, and he still lives at Shirley.

NAMES OF FRUIT.—Mrs. Crosse.—1, Allington Pippin; 2, Hanwell Souring; 3, Wyken Pippin; 4, Wellington; 5, Lane's Prince Albert; 6, King of the Pippins; 7, Beauty of Hants.—J. H. Pepper.—1, Beauty of Kent; 2, Pott's Seedling; 3, Annie Elizabeth; 4, Mère du Ménage; 5, Pine-apple Russet. Pears: 1, Pitmaston Duchess; 2, Marie Louise.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

To say that the fortnightly meeting held on December 1 was distinctly above the average of normal times for the season of the year is to indicate that every available inch of space in the great exhibition hall at Vincent Square was packed to its utmost extent, visitors, too, being in like proportion. Doubtless to some extent the oncoming exhibition of winter-flowering Carnations was responsible, though the announcement of a fruit show to replace in some measure that usually held in October was by far the greater attraction. The collections of fruit, indeed, were the outstanding feature of a great meeting, fruit of the highest excellence and finish, that did ample justice to this increasingly valuable British industry. Another imposing feature was a great bank of Begonia Gloire de Lorraine from a private garden, which deservedly gained a gold medal. It was probably the finest thing of its kind yet staged. The Orchid and floral committees each gave an award of merit to one novelty.

ORCHID COMMITTEE.

Present: J. Gurney Fowler, Esq. (chairman), Sir Harry J. Veitch, Sir Jeremiah Colman, and Messrs. J. O'Brien, J. Wilson Potter, F. J. Hanbury, R. Thwaites, R. A. Rolfe, W. Cobb, F. M. Ogilvie, J. Charlesworth, C. H. Curtis, W. H. Bound, A. Dye, J. E. Shill, W. H. White, S. W. Flory, W. Bolton, Gurney Wilson and R. B. White.

Only a few groups of Orchids were staged, though they included many beautiful kinds. Messrs. J. and A. McBean, Cooksbridge, had a variety of hybrid Odontiodas, some very beautiful Odontoglossum crispum, the crimson and white Cymbidium Alexanderi, Lælio-Cattleya Auto

Doin and the very old though useful and distinct Zygopetalum Mackayi. Cattleya Fabia alba was also very beautiful and chaste-looking. Silver Banksian medal.

In a rather extensive display Messrs. Stuart Low and Co., Jarvisbrook, Sussex, had a very fine example of Vanda sanderiana, some beautiful sprays of V. cærulea, Cattleya labiata reedleyensis (a lovely white form), Lælio-Cattleya luminosa (of orange and crimson colouring), Sophro-Cattleya Doris (intensely rich cerise), Cattleya aurea, C. Raphaelæ alba and Lælio-Cattleya Eldorado gigas, which was very fine. The new Brasso-Cattleya Pink Pearl (see "New and Rare Plants") was also shown by this firm. Silver Banksian medal.

Messrs. Sander and Sons, St. Albans, showed very fine specimens of Cypripedium Sanderæ, Cattleya Dusseldorffii Undine, Cattleya Fabia alba, Lælio-Cattleya primulina (yellow sepals and crimson brown, much-veined lip), together with Cœlogyne mooreana (white) and a pleasing variety of Odontoglossums. Cypripedium Corsair was also among kinds of distinctive merit. Silver Flora medal.

Messrs. Charlesworth and Co., Hayward's Heath, had a few very beautiful and choice plants, the more conspicuous being Cattleya Venus, whose sepals and petals have an almost unique blending of salmon and pale rose, a remarkable combination which attracts immediately, the crimson brown lip being in fine contrast. Miltonia bleuana was well represented; Lælio-Cattleya Bella alba, very chaste; Odontioda Brewii, intense crimson; Oncidium cheiroporum, small yellow flowers; a variety of Odontoglossum crispum; and Cochlidia miniata, whose inflorescence of pinky red flowers was very charming. Silver Flora medal.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. E. A. Bowles, R. Hooper Pearson, J. Green, W. J. Bean, R. C. Notcutt, G. Reuthe, C. Blick, J. W. Moorman, F. W. Harvey, C. R. Fielder, J. Hudson, J. W. Barr, W. Howe, J. F. McLeod, W. H. Page, J. Jennings, W. Bain, W. Cuthbertson, J. Dickson, C. Dixon, A. Turner, J. T. Bennett-Poë, Charles E. Shea, Charles E. Pearson, W. P. Thomson, E. H. Jenkins, G. Paul and W. G. Baker.

Messrs. Allwood Brothers staged an admirable lot of Carnations, making a great centre-piece of Wivelstfield White, which was in superb form, the handsome flowers showing well. Fairmount (heliotrope self), Mary Allwood (cardinal pink), British Triumph and Princess Dagmar (crimson), May Day (pink), Champion (scarlet) and Philadelphia (cerise pink) were others in a notable lot.

Messrs. Stuart Low and Co., Enfield, showed a full-length table of Begonias and Carnations, the former typified in such as Optima (pale orange), Rosamund (cerise), Exquisite (salmon and white) and Emita (deep orange). The Carnations, displayed in goodly stands, included Snowstorm (white), British Triumph, Princess Dagmar, Mrs. Mackay Edgar (a superb pink in a central place) and Champion. Gorgeous (deep cerise) was also very fine.

Mr. C. Engelmann, Saffron Walden, had a table of Carnations, occupying the whole of the western end of the hall, a great number of varieties being staged. The exhibit was rather in the nature of a collection, and we fancy we have seen better material from this well-known exhibitor. Pioneer (cerise), Lady Northcliffe, Red Sport Lady Northcliffe, Bella (orange and white), Benora (fancy), Yellow Stone, Gorgeous, Scarlet Carola, Sunstar (yellow, very good), Carola (very fine), Variegated Carola, Mrs. C. F. Raphael (scarlet), Rosette and Enchantress Supreme were others in a large lot. Some eighty varieties were staged.

Mr. Clarence Elliott, Stevenage, had a nicely grown plant of Iris stylosa in flower, also a few plants of Soldanella pusilla alba, with gentian flowers, in a collection of alpine and rock shrubs.

Mr. G. Reuthe, Keston, Kent, showed a large collection of alpine (not in flower), together with a nice assortment of Nerines, Iris Vartani, I. alata, the lovely Crocus marathonsius (very pure white), C. media, C. longiflorus (rosy mauve), C. ochroleucus (white, yellow base) and C. cartwrightianus (white, with purplish lines at base and brilliant orange stigmata). Hardy Heaths were also shown.

Mr. A. F. Dutton, Iver, Bucks, arranged a large collection of Carnations in ornamental baskets; indeed, we thought the latter overdone and too much in evidence. The flowers were, however, very fine. May Day, Beacon, Enchantress Supreme, Sunstar, White Enchantress, White Wonder, Queen Alexandra (fine pink) and Princess Dagmar (crimson) were the best.

The Misses Hopkins, Shepperton-on-Thames, set up planted boxes of select alpine, a revival of an idea in vogue many years ago. Saxifrages, Dianthi, Gentians, Thymes, Campanulas, Primulas and many others were employed in this way with pretty effect.

Mr. L. R. Russell, Richmond, set up a large exhibit of berried shrubs—Skimmia, Aucuba, Crataegus and the like. Begonias of the Gloire de Lorraine type were also shown.

The Misses Tate and Tanner, Bushey Heath, Herts (gardener, Mr. Streeter), exhibited a superb group of winter-flowering Begonias, in all probability the finest of its kind yet staged. The majority of the plants were in specimen form, particularly those of the Gloire de Lorraine section, of which the group was chiefly composed. These were in the various shades of pink and the white-flowered forms, the plants being 2½ feet high and the same through in the majority of instances. Cliban's Pink, Altrincham Pink and Miss Cliban, of the winter-flowering set, were also in evidence, and afforded variety and importance to a group lacking nothing in culture and good staging. A gold medal was deservedly awarded.

THE GARDEN.

No. 2248.—VOL. LXXVIII.

DECEMBER 19, 1914.

NOTES OF THE WEEK.

Kew Guild Men in the Army.—A list of members of the Kew Guild serving with His Majesty's Forces is in course of preparation for publication in the next Journal to be issued in January. Information, to include the name of the regiment to which they are attached, from members or their friends should be sent to Mr. A. Osborn, 191, Kew Road, Richmond, Surrey.

The Christmas Daisy.—Only when we get a mild late autumn is the beauty of *Aster grandiflorus* seen in the open ground. This is unfortunate, as it is one of the most beautiful species of the genus. A good plan is to treat it as a pot plant, giving it the same conditions as Chrysanthemums, either growing it on in pots or lifting it from the ground early. In this way it can be had in perfection, when its beautiful blue flowers make a striking contrast to white and yellow Chrysanthemums for decorating the conservatory. Its late-flowering qualities also make it very valuable for cutting.

A New Oil-Seed from South America.—The current issue of the *Kew Bulletin* contains some interesting particulars of a new oil-seed from South America. This is the seed of the tree known as *Osteophloeum platyspermum*, or *Myristica platysperma*, a native of North-West Brazil, where it was discovered by Spruce in 1852. The fat obtained on extraction with petroleum ether is white and crystalline, with a slight smell, and the seeds give the very high yield of 55.2 per cent. of fat. Now that there is such a large demand for all kinds of vegetable fat, the discovery of this new source should prove of considerable commercial value. At present the Kew authorities have no information as to the quantity of seeds likely to be available.

The Dean Hole Memorial Medal.—It is with considerable pleasure we learn that the National Rose Society, at the annual meeting held on Thursday of last week, conferred the Dean Hole Memorial Medal on Mr. C. E. Shea of Foot's Cray, Kent, whose portrait we publish on this page. On two separate occasions Mr. Shea has acted as president of the society, viz., during 1905-6 and 1913-14. His services in the interests of the Rose and the National Society have extended over a very long period, and his genial and courteous manner has made him one of the best loved and most highly esteemed men in the horticultural world. The Dean Hole Memorial Medal is the highest honour that the National Rose Society can confer, and everyone who is privileged to know Mr. Shea will agree that he thoroughly deserves this distinction.

Planting Trees and Shrubs.—Although November is undoubtedly the best month of the whole year for planting practically all kinds of deciduous

trees and shrubs, including fruit trees, it does not follow that they cannot be successfully planted at any other time. Providing the weather keeps open and the soil is in fairly good working condition, such trees and shrubs can be safely and successfully planted at any time from early November until March. We mention this now because, during recent years, so many lecturers and other horticultural instructors have emphasised the desirability of November planting, with the result that many amateurs have erroneously come

of soil, and placed in a little warmth. If this is continued at intervals, a good supply will be maintained; or if a frame is placed over the bed, it will give a good quantity before the Mint in the open ground is ready.

Fruit for Christmas.—Notwithstanding the war, there is likely to be an abundance of nearly all kinds of fruit for Christmas, with the exception of dried Dates and Figs and crystallised fruit. Covent Garden supplies are excellent, and owing to the fact that they cannot be shipped to Germany or Austria, Pineapples and Bananas will probably be cheaper than for some years past. Pineapples have never been of better quality. Nuts, too, are plentiful, the much sought after Brazils being cheaper than for some years past.

***Pyracantha angustifolia* for Winter Beauty.**—When this plant was originally introduced under the name of *Cotoneaster angustifolia*, it was usually planted as a shrub in the open, and rarely with satisfactory results. On one or two occasions, however, fruiting specimens were sent from France to this country, and such was their beauty that cultivators were stimulated to fresh efforts in their endeavour to find the conditions suitable for its culture. This object has now been attained, and as a wall shrub it promises to become as useful as its older relative the *Pyracantha* of gardens, *P. coccinea*, or *Cratægus Pyracantha* as it is also called. *P. angustifolia* grows at least 12 feet high and bears narrow, oblong, evergreen leaves up to 2 inches long and one-third of an inch or more wide, the flowers being white and followed by a profusion of orange-coloured berries, which ripen in October. It is a native of Western China, and was introduced to this country by Lieutenant Jones fifteen years ago. It should be planted in rather light and well-drained loamy soil at the foot of a south, west or east wall, and in such a position it may be expected to provide a very cheerful picture from October to January or later. As it is less hardy than the common *Pyracantha*, it should not be planted in places where the last-named shrub is known to be a failure.

***Rosa spinosissima* (Scotch or Burnet Rose).**

Last summer we had the pleasure of finding this growing wild on a common not far from Worthing, where on a dry, poor and gravelly soil mingling with Heather, wild Sage and the rapidly oncoming Bracken, it, though brought into subjection, constituted a very pretty picture in satiny white. Reduced by circumstances into comparative dwariness—it was often of less than a foot high and rarely more than 18 inches—it was still suggestive of good use, and we pictured it in the rock garden similarly starved to produce effect.

MR. C. E. SHEA, WHO RECEIVED THE DEAN HOLE MEMORIAL MEDAL FROM THE NATIONAL ROSE SOCIETY LAST WEEK.

to regard it as the only planting-time. The same remarks apply to nearly all kinds of hardy herbaceous plants, hence those who wish to plant from now onwards need not refrain from doing so.

Fresh Mint for Winter Use.—This is always preferred to dried Mint, but seldom during the winter and early spring months is the supply of this useful herb equal to the demand. Pieces of roots should now be lifted, put in shallow boxes

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Late-Blooming Roses and Oriental Lilies in South-Western Scotland.—The Rev. David R. Williamson writes us as follows from Kirkmaiden Manse, Wigtownshire, on December 7: "Roses have flowered very late in my garden this year. Conspicuous among these have been Viscountess Folkestone, notable alike for its free-flowering capabilities, its charming pale salmon pink complexion and its exquisite fragrance—a Hybrid Tea of inestimable value, at least in my own estimation, and one that will not be soon superseded; Bouquet d'Or, perhaps the most precious of all the beautiful daughters of Gloire de Dijon, a plant of which has adorned a wall with a northern aspect for at least fifteen years; Margaret Dickson, by far the most aspiring Rose

is generally supposed to be a derivative from Melpomene."

Late-Flowering Kniphofias.—We have had a bed of the late-flowering Torch Lily (*Kniphofia aloides glaucescens*)—misnamed *maxima* in your note of the 5th inst., page 583—for about ten years, and every season in November it is the most striking plant in the nursery. The rains and night frosts that bedraggle the Michaelmas Daisies have no effect on it, and even now it is a fine mass of colour, as you will see from the spikes sent you under separate cover. It should be planted in masses of a dozen or more, in beds cut in the grass, and placed so that, when in flower, the heads show up against some dark evergreen or piece of woodland. Then it is extremely effective. It is odd that it should always flower so late, when there is no chance of setting seed; but it makes no show of spikes before September. We took a special interest in this family for some years, and raised a number of very pretty seedlings in which a long-

COPRINUS (AGARICUS) COMATUS, A FUNGUS THAT IS EDIBLE WHEN YOUNG.

that I possess, and that is saying much; J. B. Clark; Captain Hayward, which among crimson Roses is quite indispensable; and the supremely attractive Pharisæer. The variety last mentioned, I may incidentally mention, particularly attracted the attention and elicited the admiration of the Countess of Stair when she visited my garden a few years ago; and subsequently, at my suggestion, her ladyship (who is an assiduous amateur horticulturist) added this highly effective variety to her interesting collection at Lochinch Castle, where she also cultivates with marvellous success in her shady wild garden almost all the leading species of Oriental Lilies, especially the Himalayan *Lilium giganteum* and *L. auratum platyphyllum*. I may perhaps be permitted to add that a fine specimen of *L. speciosum magnificum* was flowering in my garden this season at the end of November, the latest I have ever seen it, at least in this region. This grand variety, which grows admirably in ordinary garden loam

flowering habit is secured. Perhaps Gold Else and Torchlight are the best known. These flower more or less continuously right through the summer and autumn, and both are extremely pretty for cutting in October, when there is very little else of this colour in the garden. Two October-flowering species are also worth wider cultivation—*breviflora*, which is pure yellow, and *Nelsonii*, which is scarlet. They have delightful grassy foliage, and when happy throw up flower-spikes in great profusion. Unique is a *Nelsonii* hybrid for which we obtained an award in 1912. It has flowers of a glaucous coral, without a touch of yellow, and is very handsome with the grassy *Nelsonii* foliage. A strong plant will carry over twenty spikes. Then *Kniphofia aloides glaucescens* comes last of all, a stout, bold grower, 4 feet high, with broad foliage.—R. WALLACE AND CO., Colchester. [The plants at Kew to which we referred in our issue for the 5th inst. are, or were, labelled *K. aloides maxima*. It, as Messrs. Wallace state, this is incorrect, we

may expect the Kew authorities to put the name right.—Ed.]

Agaricus comatus.—We have had—to mention—extraordinary crops of this most delicious of esculent fungi. They appear about the middle of November for a fortnight or three weeks upon a steeply sloping wooded bank above the river Vyrnwy. Curiously, they come only in one place—a strip down the bank about ten yards wide and perhaps twice as long. I have not found even isolated specimens elsewhere, though there are stretches of similar bank along the course of the river. It happens that down this particular strip of the bank were cast, in the spring of 1912, many loads of limestone rock for use on the river bank. Can this have caused the growth of *A. comatus*? I do not think they appeared previously, but cannot be certain, as we were not here till towards the end of November, 1911, and people whose interest has not been aroused do not notice such things. The soil is of the poorest, the timber chiefly Oak. The profusion of the crop is such that every two or three days while they last we can gather a dish of six or eight. I enclose a photograph of one of this year's groups—not nearly so fine as last year's, however, when we gathered many of which the pileus was over four inches in length, and some, I should think, nearly six inches. Is anything known of the conditions necessary to the growth of this fungus?—C. H. CUMBERLAND, *Plás Derwen, Llansantffraid, Montgomeryshire*. [We have submitted the above to our scientific expert, who writes as follows: "Agaricus comatus is the old name. It is now *Coprinus comatus*. Only quite young specimens should be eaten or used for making ketchup."—Ed.]

Banksian Roses: How to Make Them Flower.—In reading THE GARDEN for December 5, page 588, respecting Banksian Roses, I thought I would write to tell you that in my father's old rectory garden at Bonnington, Kent, we had a very old Yellow Banksian Rose tree which grew all over the south porch. In all the forty years he was there this old tree blossomed profusely, and I think I am right in saying that it never was properly pruned, its roots were never dug and never manured in all that time, and it grew in the coldest of cold clay soil.—ALICE S. ROLFE.

— It may interest your correspondent "A. B. Essex" to know there is a white Banksian Rose here which flowers profusely every year. It was planted nearly a hundred years ago by my uncle. It certainly carries out the theory that these Roses flower best when they receive little or no attention. This tree is planted in the grass close to the south wall of the house, not even in a flower border. Its roots must go under a gravel path and the lawn, as there are no flower-beds near. It covers most of the side of that wing, and is never touched, except to cut back shoots which grow too long and tie them in. We planted another Banksian Rose two or three years ago on a south wall in the kitchen garden; but the soil there is evidently too good, for though it has grown most luxuriantly and reaches to the top of the wall, it only has two or three trusses of flowers each summer. I must add that our soil here is very stiff clay, and we are about a mile from the sea.—MARY C. BOND, *Tyncham, Corfe Castle, Dorset*.

— I see a request in THE GARDEN for experiences with Banksian Roses. I have two

common ones, a yellow and a white. The white faces south and the yellow east. The white was a sheet of blossom this year, the yellow flowered fairly well; but, then, this year was marked by great floriferousness. However, by pruning regularly after they have flowered, they do sufficiently well in ordinary years. I have the old wood taken out. That may be wrong, possibly, if one wants flowers, but room must be made for the young wood. Twice when I ordered the common Banksian Rose I was sent Fortune's Yellow. I did not care for it. It is a shy bloomer, and drops many of the few buds it makes. But whereas a south wall is necessary to get the best results from the common Banksian, I found Fortune's Yellow did better on a north wall. It might be worth while to try growing it up a tree.—F. G. DUTTON, *Bibury Vicarage, Fairford, near Cirencester.*

— My experience leads me to the conclusion that to get Banksian Roses to flower well, it is best to let them run practically wild. I have seen them growing very well indeed in various aspects—north, south, south-west and east—somewhat protected in the last named; but on very poor soil and in a very confined corner of a shrubbery close to the house, about a foot from the gravel drive, they flowered most profusely. In the other aspects named they had plenty of root room. Quite open in other respects (as they were planted on houses with the lawns in front of them), they were kept well trimmed, but gave very few flowers indeed; in fact, one on the north aspect did not have any flowers. I might say that those planted on the south and south-west aspects (both the white and yellow) I did not have charge of, but I was there as undergardener for ten years and noticed them with very few flowers. The north and east aspects were in Sussex, the south and south-west in Surrey (at Dorking).—E. TRING.

Christmas Decorations: Some Suggestions.—

For the table: Red and yellow Tulips or Chrysanthemums in little black enamelled baskets for Belgian colours. Red and white Tulips, Hyacinths or Chrysanthemums and Violets, for English, French and Russian colours. A quaint and unconventional table centre, easily "kept going" all through Christmas-time, can be made with a tin or tray as foundation. On this crumple up irregularly some coarse-meshed wire-netting, leaving several depressions. Cover all with fresh moss and trails of Ivy, and in hidden receptacles containing water place Holly, Mistletoe, flowers, seedling Ferns, &c. In the centre sink a tiny oil lamp or "fairy light" to shine through the flowers and foliage. Border the whole with a garland of fine Ivy trails and (do not laugh!) frost over all with a sprinkling of coarse Epsom salts. For Christmas pictures from the illustrated Christmas numbers, an artistic border is quickly and easily made by tacking dried brown Oak leaves slightly overlapping each other on half-inch wide strips of brown paper. These have the effect of leather-work or carved Oak frames. Always carry each stitch across the midrib of the leaves, laying the tip of one leaf over the stalk of the preceding one and stitching both together. One stitch to each leaf is generally enough. For bare wall spaces, an effective trellis can be made by wiring trails of Ivy, interspersed with other evergreens. This is very ornamental for covering bare or unsightly walls, and is useful for decorating halls and schoolrooms for Christmas entertainments.—ANNE AMATEUR.

MR. E. MAWLEY AND THE NATIONAL ROSE SOCIETY.

IT was with very deep regret that the members of the National Rose Society learned, at the annual general meeting held in London on Thursday of last week, that Mr. E. Mawley, V.M.H., had felt compelled to relinquish the office of hon. secretary. This regret, however, was somewhat tempered by the enthusiastic election of Mr. Mawley as president for the ensuing year.

His association with Roses and the National Rose Society dates back a very long way. It was about the year 1875 that he first commenced to grow Roses at Croydon, and in 1877 he became co-hon. secretary of the National Rose Society with the late Rev. H. D'ombrain. When that esteemed rosarian died in 1905, Mr. Mawley took over the full duties of hon. secretary. He

MR. E. MAWLEY, V.M.H., FOR MANY YEARS HON. SECRETARY OF THE NATIONAL ROSE SOCIETY AND NOW PRESIDENT.

has endeared himself to all those who have had the privilege of meeting him since his official association with the National Rose Society, and has had the satisfaction of seeing it grow from a small association into the largest special floricultural society in the world.

In his younger days he was a very keen exhibitor at the society's shows, and so successful was he in taking prizes in the smaller classes that his friends used to affectionately refer to him as the "champion of lightweights." In 1885 Mr. Mawley moved from Croydon to Berkhamsted, a town that has been privileged to number him among its residents ever since. As an appreciation of his services to the National Rose Society the members unanimously bestowed upon him, in 1910, the Dean Hole medal, a special distinction which is awarded from time to time as occasion may arise.

In the past he has also been a very active worker on behalf of the National Dahlia Society, and for

several years was its president. Meteorology also claimed Mr. Mawley's attention, and for thirty years he was a member of the Council of the Royal Meteorological Society, and for two years secretary, ultimately becoming its president in 1904. The Council of the Royal Horticultural Society, in recognition of his services to horticulture generally, conferred upon him the Victoria Medal of Honour in Horticulture in 1904. Just what the National Rose Society owes to him perhaps will never be known; but we feel sure that everyone who is interested in Roses will regret that he has been reluctantly compelled to relinquish the hon. secretaryship, and will join with us in wishing him many years of further activity and enjoyment of the flower he loves so well.

ROSES IN YORKSHIRE.

(Continued from page 597.)

WHEN we look round at the many beautiful varieties of yellow and orange toned Roses our gardens contain to-day, it seems almost impossible to realise that only five years ago many of the best of these were not in existence. Duchess of Wellington, Mabel Drew, Mme. Charles Lutaud, Mrs. C. E. Allan, Lady Hillingdon, Mrs. Sam Ross, Lady Downe, Lady Greenall, Cissie Easlea and Sunburst, to name only a few, have all appeared since 1909. Six of the above I have only just planted, and am therefore unable to speak from practical experience; but I am confident that many of them will do well, and impatiently await their development next summer.

The yellow *par excellence* with me the last two years has been Duchess of Wellington, a fine, free grower that produces blooms in abundance of a charming yellow, splashed here and there with red, more especially in the bud state. Although this Rose is composed of very many petals, it has opened well, thus proving the exception to the rule of the Rose with few petals as *the* Rose for this vicinity; moreover, the blooms are held on fine, stiff stems and are deliciously fragrant. It is quite free from mildew. I cut a bloom on November 28, and still there were buds to develop if the weather chances to be kind to them.

Next comes Mme. Ravary, one of the hardest and best of any colour or variety; a very free bloomer that produces lovely golden buds, developing in the half-open state to deep apricot. When fully expanded it pales off rather too soon, but is in every way a most excellent Rose. Sunburst is rapidly becoming a favourite and, except for its extreme variableness of colour, is a good doer here. Harry Kirk, one of the finest of the pure sulphur yellows, is indispensable in this section for its decorative value, and it may be planted here with confidence. Mrs. David McKee, a fine Rose of a beautiful creamy yellow shade, produces freely blooms of an immense size and pleasing shape; it is in flower here throughout the season. It is vigorous, decorative, fragrant and gives one blooms fit for exhibition.

Among the coppery tones, the best with me have been Edu Meyer, a rather poor grower, but an abundant bloomer, and, moreover, the flowers last a very long time when fully expanded on the plants, continually providing a pleasing touch of colour in its own particular bed all the season; and Betty, to which I referred in my first

article. This is one of the indispensable decorative Roses, and belongs to the first dozen every amateur should order when he embarks upon the cultivation of the Rose. Its colour is made up of beautiful tones in copper, shaded golden. It is very vigorous, an excellent bedder, and has the added charm of fragrance.

It would be unpardonable to put Frau Karl Druschki anywhere else than at the top of the list in the white class. It has so many virtues and only one fault, in that it is absolutely without perfume. This is such a disappointment, because its wonderful size and shape and spotless purity of petal all make it so attractive for all purposes. It appears in the exhibition box, I suppose, more often than any other variety of any class or colour. It is a very free grower here, and is, happily, not seriously affected by wind and wet. One of my few standards is of this Rose, set in the centre

tints, however, but like it none the less for that. It produces large quantities of most decorative Roses, which last well on the tree, and is another variety always in bloom.

Juliet here is a Rose that is distinct and novel in both colour and growth; outside of petals old gold, inside vermilion. Growth is extremely vigorous. I confess I planted this with some hesitation; so many people like myself, amateurs, complained of being dissatisfied with the results. However, I pegged down the three long growths of which the plant consisted, and took about eight inches off the end of each when pruning. Judge of my surprised delight when I perceived buds in abundance coming along the entire length of each branch, and I had eventually no fewer than thirty-three Roses out or partially out in bloom at one time, and the effect in the centre of an oblong bed was most pleasing. The buds are

to the numbers of those that do well. My leisure time is extremely limited, and I am only able to indulge my love of Roses by leaving everything else in the garden to the tender mercies of a jobbing gardener.

Among the unsuccessful Rose-growers we find a great proportion of those who refer to planting Roses as "sticking them in." The man who "sticks" Roses in will never succeed in producing fine blooms, nor does he deserve to do so. It is just that extra trouble and extra barrow of leaf-mould to sprinkle over the fibrous roots when planting, and the plunging of the dried roots and growths into tepid water, seemingly unimportant details, which are great factors to the Rose tree, likewise the subsequent pruning and attention to various pests, &c. Finally, I believe most emphatically in the value of liquid manure for Roses, from the bud stage onwards. A generous supply after heavy rain goes far towards maintaining colour in the blooms. E. WATERS.

Roundhay, near Leeds.

THE SMOKE PLANT (RHUS COTINUS) IN AUTUMN. THIS HARDY SHRUB WILL THRIVE IN ALMOST ANY SOIL.

of a bed of Gloire de Chedane Guinoisseau, which has given to it a perfect finish.

British Queen I have only had one year, and it has done well and been continuously in bloom. The flowers are of fine size and very fragrant. I must admit that I had quite a number of blooms of very bad shape, and it has been rather badly affected with mildew; further, it is whispered that the best results from British Queen are forthcoming from maiden plants. If that is so, it will with me have to give place to Mrs. Herbert Stevens, which up to now I have not grown, but find it does very well in my district, and I have planted it this autumn.

Viscountess Folkestone is, of course, not a white, but does so well with me that I mention it here as a Rose that is reliable in a Northern climate. Some of the catalogues describe it as "creamy pink, shaded salmon." I get none of the salmon

vigorous and nearly as large as Walnuts. When open it is a large, full Rose of powerful and delicious fragrance. I find that many amateurs allow this to grow tall, and consequently get only four or five blooms during the season. It is a Rose that wants plenty of room, and its only fault is a tendency to mildew on the thorns and nowhere else. The foliage is clean.

I find that Dorothy Perkins and its white sport, also Hiawatha, Excelsa, Alberic Barbier and Tausendschön, are reliable and free among the climbers here. Crimson Rambler is an absolute failure so far as growth is concerned, and I am gradually replacing it with Excelsa.

In conclusion, as a man of Kent living in Yorkshire, I would say that, so far from being disappointed with my experiences in the cultivation of Roses, I am keener than ever to go on, profiting by mistakes in the selection of varieties and adding

THE SMOKE PLANT (RHUS COTINUS).

DURING the autumn months there are few more attractive hardy shrubs than the Smoke Plant (*Rhus Cotinus*). At that season the feathery inflorescences impart to the shrub a very peculiar appearance that, at a distance, looks somewhat like a cloud of smoke, this effect being well shown in the accompanying illustration. Although introduced to this country as long ago as 1656, one does not often find this shrub in gardens, a fact that is rather difficult to understand. It is perfectly hardy and will thrive in almost any soil, but, as it makes rampant growth, it should be planted where plenty of space is available. According to Nicholson, the preparation known as Young Fustic is obtained from this *Rhus*, which, in some districts, is known as the Yellow Dye-wood.

SHRUBBERY BORDERS IN WINTER.

THESE are rarely treated as they should be in autumn and winter time. Shrubberies are to a dwelling-house what frames are to pictures, in a sense, only they are of much more importance. There is a very economical way of feeding the shrubs without using any ordinary manures. Where there are trees of a deciduous character in a garden, the leaves from them get blown on to the shrubbery borders, and in nearly every instance the leaves are raked off and taken to a common rubbish-heap, and the surface soil among the shrubs dug up. In the case of old shrubberies this is wrong treatment. The digging makes the shrubbery look neat and well cared for, but it is at the expense of the welfare of the shrubs, as all their surface roots are destroyed and the others are not enriched. In the case of young shrubs, where there is ample space between them not occupied by roots, the digging will have a beneficial

effect. In dealing with other shrubberies, the leaves collected among the stems of the shrubs should be picked out, all hollows filled with the leaves, and the latter covered with a thin layer of soil from another part of the garden. No more work than the digging of the border will be entailed, the shrubbery will present a very neat appearance, and the shrubs will greatly benefit, as their roots will enter the mulch and form a network. The soil put on prevents the birds and wind disturbing the dry leaves, and also assists in the process of decay. Where the leaves are too numerous, the surplus can be used for forming leaf-mould.

AVON.

THE MAIDENHAIR TREE

(GINKGO BILOBA.)

ALTHOUGH a well-grown specimen of this tree never fails to elicit admiration from anyone interested in gardening, it is seldom that we see young trees planted. It is true that they are rather slow-growing, but the same may be said of a good many others that are much more frequently planted, although not so beautiful in appearance. The Maidenhair Tree is quite hardy in the Southern and Western Counties of Great Britain, where it will thrive in almost any good garden soil. In France trees that have attained a good size and age produce fruits fairly regularly, but it is not often that these are borne in this country. It is a coniferous tree, though deciduous, and one of the oldest in existence, remains having, I believe, been found in coal measures in some parts of the world. It was introduced to this country from Northern China in 1754, and is often known under its old botanical name of *Salisburia adiantifolia*. Its garden name is derived from the resemblance of the leaves to the pinnæ of some of the larger *Adiantums* or Maidenhair Ferns.

G. B. D.

SWEET PEAS IN POTS.

FINER and earlier blooms are secured from plants grown in pots during the winter months than from those raised in spring. Such has been my experience. Of course, other cultivators may not agree, yet I think many will. I depend entirely on the basal shoots that grow on the young plants for the finest flowers, and these basal shoots should be encouraged to grow strongly from the latter part of December onwards. The seeds are sown in September or, at the latest, before the middle of October. Two seeds are sufficient for a $3\frac{1}{2}$ -inch pot, and one seed for a 3-inch pot. Good fibrous loam is used, with equal parts of leaf-soil and well-rotted manure placed in the bottom of the pots. Crocks are not needed if the pots are placed on ashes or boards. The pots are placed in a cold frame, the soil kept in a uniformly moist condition, and, when the young plants appear, air is admitted in abundance and the plants exposed to full sunshine.

Feeding at this stage is not necessary; the rotted manure in the bottom of the pots affords the plants all the sustenance they need. They may be retained in the frame all the winter, but I prefer to place them on a shelf in a greenhouse about 1 foot or 15 inches from the roof glass, and where air can reach them in abundance during fine weather. Late in November the plants have attained a height of 7 inches; they are not staked or kept in an upright position, but allowed to depend from the sides of the pots towards the light. When left in this way, strong basal shoots soon begin

FLOWERS FOR CHRISTMAS DECORATION.

ALTHOUGH Holly, Mistletoe, Laurel and other evergreen shrubs still play an important part in our Christmas decorations, there is a rapidly increasing tendency to incorporate with these the numerous flowers that are now available at this season. Improved methods of cultivation and the introducing or raising of new types of plants that naturally flower during the winter months have, no doubt, had a great deal to do with this change. This year, owing to the exceptionally mild weather, there should be an abundance of most greenhouse winter-flowering plants, because strong artificial heat has not been necessary. Even in the outdoor garden such flowers as Christmas Roses, *Irises stylosa* and *reticulata*, *Snowdrops*, *Wallflowers*, *Violets*, *Daisies*, and possibly a few *Roses* will be available for cutting at Christmas; but it is on the indoor kinds that we must rely for sufficient to create really good effects. As cut flowers there are few kinds to equal the Perpetual-flowering *Carnations*. About twelve or fifteen years ago these were only to be found in a few gardens; now they are grown in startlingly large quantities for market purposes, and there are few private gardens in which a collection cannot be found. As they are to be had in several shades of pink, crimson, scarlet and white, they lend themselves well to nearly all kinds of decoration, and look particularly charming under artificial light. *Chrysanthemums*, especially the small double varieties and the singles, are becoming increasingly popular. There are now some delightful shades of bronze, yellow, crimson, pink and pure white, and nearly all mix well with evergreens where a bold effect is desired. For filling large vases or pitchers for standing in the corners of halls or corridors, the large-flowered *Chrysanthemums* are very useful, and they can be obtained in a sufficiently wide range of colours to suit almost any scheme. *Violets*, *Paper-White Narcissi*, *Scarlet Duc Van Thol*

THE MAIDENHAIR TREE (GINKGO BILOBA) AT KEW.

to grow as stated. If grown in borders under glass, the soil is deeply broken up and some well-rotted manure mixed with it. If grown in large pots, these are filled with fibrous loam, a small quantity of leaf-soil and some rotted manure. In such mixtures the plants grow steadily and sturdily, and rarely cast their first flower-buds. Other kinds of stimulants are not given until the plants commence to flower, as I believe it to be a mistake to force growth in the depth of winter. Plants intended for the open borders should be replaced in the cold frames early in February, and be well hardened before they are put out in April.

The plants must not be subjected to high temperatures nor to frost.

G. G.

Tulips, *Lilium longiflorum*, *Arum Lilies* and *Poinsettias* are other kinds which are grown in quantity in most good gardens, and which will also be obtainable in the market should it be found necessary to purchase them.

Of pot plants there are some very delightful kinds to select from. Perhaps the most charming and useful of all is the dainty pink-flowered *Begonia Gloire de Lorraine*. This can be had in many sizes, from a tiny plant a few inches high to a floral pyramid that measures nearly two feet from base to summit, as well as in baskets that are suitable for hanging in almost any position that may be necessary. This *Begonia* looks exceptionally well under artificial light, and may be effectively

used for table decorations in conjunction with pink Carnations. There is also a white-flowered form of it, and this contrasts well with scarlet Carnations or Tulips. Although Christmas is a little early for Cyclamen, there is certain to be a fair quantity this year, owing to the exceptionally mild weather. The flowers of pure white and shades of pink can be used in a cut state if desired, though I think they always look better on the plants. Greenhouse Heaths of several kinds are always welcome for decorating large tables. *Erica hyemalis* is a rather tall, erect plant with tubular-shaped pink and white flowers, but *E. gracilis* is usually the most popular, owing to its closer resemblance to the Heather of the moors. It is grown for market in little pots, where it forms a veritable bush of fragrant flowers. Larger sizes are also grown, but it is the small specimens that seem to be most appreciated. H. H.

THE LUPINES.

DURING the late spring and summer months, when the whole garden is a blaze of bizarre colours, the modest charms of the various kinds of Lupines are sure of a universal and cordial welcome. Their stately spikes of blue and white flowers form pyramids of these quiet hues in large and small gardens alike, and even under the trying conditions of town life, while their Palm-like foliage is ever a source of wonder to children and soothing to those who have long since passed the happy days of childhood.

The ordinary form of the herbaceous Lupine known as *Lupinus polyphyllus* has been grown in our gardens almost from time immemorial, yet it is still one of the best and most generous hardy plants that we have. Its flowers are a mixture of porcelain blue and white, a combination that is not too common among our hardy flowers. There is now a variety with pure white flowers which is useful under some conditions; and during recent years hybridists have raised a number of sorts with flowers of old rose or dull pink colour, so that with these plants alone a varied display can be obtained in late spring and early summer, and again in the autumn. To secure flowers at the last-named season, however, it is necessary to cut down the plants almost level with the soil as soon as the first display is over, and subsequently give them a rather heavy mulching with manure and generous supplies of water.

Of quite different habit is the so-called Tree Lupine, *Lupinus arboreus*. This is an ideal plant for growing in rather poor soil, as this semi-starvation tends to harden the shoots, which are thus able to withstand the frosts of winter. It forms a bush from 5 feet to 8 feet high, and during early summer is transformed into a cone-shaped mass of brilliant gold. The leaves of this Lupine

are similar in shape to those of the herbaceous kind, but smaller and of more silky texture. In addition to the golden-flowered type there is a beautiful white variety named Snow Queen; but this, however, does not, in most gardens, flower so lavishly as its prototype. Young plants of the Tree Lupine frequently grow from self-sown seed, and if they survive the first two winters it is rarely that they are sufficiently injured by frost as to be killed outright, at least in the Southern and Western Counties of England.

The annual Lupines are of comparatively small stature, and give us flowers in late summer and early autumn, when the more stately kinds have finished their first display. They can be had in a

THE HERBACEOUS LUPINE (*LUPINUS POLYPHYLLUS*). THIS IS ONE OF OUR BEST HARDY FLOWERS AND MAY BE PLANTED NOW.

variety of colours, and in heights ranging from 6 inches to nearly 2 feet. S.

THE RED VALERIAN AS A WALL PLANT.

ALTHOUGH not usually regarded as a plant suitable for growing in the crevices of a dry wall, the Red Valerian, as will be seen in the accompanying illustration, is well adapted for this purpose. For many years a great favourite in our best English gardens, this plant was until recently in danger of dying out, except in a few strictly rural cottage gardens, where the passing of time makes but little change. During the last decade, however, several varieties with brighter-coloured flowers have

been raised, and it would appear as though the Red Valerian was about to regain some at least of its former popularity. In the Round Tower Gardens at Windsor Castle this Valerian has in several places established itself in the retaining walls, the plants forming imposing tufts of leaf and stem that in June are transformed into masses of the rose red flowers.

SEASONABLE NOTES ON VEGETABLES.

Globe Artichokes.—Cut down the old flowering stems and remove all decaying leaves. Some protection from frost must be provided in the shape of freshly gathered leaves, 1 foot or so deep, around the stems, covered with long litter to prevent the leaves being blown away.

French Beans.—Make a sowing of five seeds in a 4-inch pot in any light compost, and place the pots in a warm house—stove, Cucumber or forcing house—in a temperature of not less than 60° by night. Directly the plants show above the soil, give them a position close to the glass in the same house to prevent the growth being drawn up weakly. As the pots become full of roots, transfer the plants to 7-inch pots, keeping them low in the pots to enable the plants later on to have a top-dressing of half-decayed horse-manure and leaf-soil, which encourages surface roots. Carefully water the plants so that they do not receive too much or too little. If the former, the roots become damaged and quickly induce the leaves to turn yellow. If, on the other hand, the roots are kept in too dry a condition, red spider quickly takes possession of the leaves, and little progress is then made. Any good forcing variety, like *Ne Plus Ultra* or *Osborne's*, answers better at this time of the year than the larger-podded sorts.

Broccoli.—To protect the plants which produce heads later on, they should be heeled over to the north by taking out a spit of soil on that side of the plant, gradually heeling it over until it lies almost flat in the trench. The soil from the north

side of the next plant will be used to cover the stem of the next, and so on, until the row is complete. Be sure that the stems are securely covered with soil, as it is this part of the plant that suffers by the action of frost, especially if the growth made during the summer has been gross.

Chicory.—Lift a sufficient number of roots and place them thickly in deep boxes or beds, where they are usually induced to grow, and blanch for salads. Any warm, moist position will suffice, and blanching is easily done by covering the plants with inverted pots.

Seakale.—Continue to place roots in the blanching quarters to maintain a regular supply of this. Where a Mushroom-house does not exist, a large box in the stokehole will suffice or a bed under

the greenhouse stage, with light excluded, will answer well. Sufficient moisture at the roots is necessary to induce quick growth, or the Seakale will be tough instead of being succulent as it should be. Freshly gathered leaves answer well for blanching, as they withhold the moisture and thoroughly exclude light and air.

Potatoes.—Early varieties should be placed in sprouting boxes in a cool, frost-proof shed, where they will be ready for the first plantings in frames or pots in the New Year. Indeed, this is a much better way of keeping all the first and second early tubers than in heaps, where they are liable to push into growth, whereby the tubers are weakened. The first shoot on a Potato, properly prepared, is undoubtedly the most essential to success. I am afraid the preparation of the seed Potatoes is a phase in the garden much neglected or, perhaps, in some quarters, little understood. It is common practice to sort out the seed tubers at digging-time, throw them in a heap in a shed, cellar, or clamp in the open, and forget all about them until they are required next year.

Herbs such as Mint, which die down annually, should have the tops neatly removed, covering the surface of the bed with half-decayed leaves, 3 inches thick, which not only protect the roots from severe frost, but enrich the soil and encourage vigorous growth next spring, besides giving to that part of the garden a tidy appearance.

Parsley in Frames should be well ventilated on all favourable occasions to prevent damp affecting the leaves or checking the growth, as this is an indispensable crop at this season of the year.

Mustard and Cress may be sown in small quantities and often to prevent a break in the supply. In boxes without a covering of soil is the most convenient method. When the seed is covered with soil, the grit is difficult to remove by washing.

Swanmore, Hants. E. MOLYNEUX.

FRUIT NOTES.

Washing and Spraying.—Although it has been proved to the point of demonstration that the efficient washing and spraying of fruit trees during their period of winter rest are advantageous, there are still many growers who will not take the trouble to practise them. If this only redounded to their own disadvantage it would not matter a scrap, but it should be borne in mind that careless or ignorant cultivators propagate pests for others, since the enemies spread from the dirty to the clean cultures. No effort ought, therefore, to be spared to persuade everyone who goes in for fruit to adopt the best measures of repressing the many insects by which the plants are attacked. When the trees are at rest it is easy to thoroughly scrub the bark to the full accessible height and to spray the remaining portion of the tree with a caustic soda wash; and if this is followed up for two or three seasons the effect in the appearance of the bark will be remarkable; and not only that, but

the tree will be in far superior health, and consequently infinitely more capable of bringing crops to perfection. The solution ought to be well brushed into all nooks and crannies of the rough bark and into the forks with a view to ensuring the death of lurking insects and, if possible, the destruction of any eggs that may have been deposited therein; but the latter is not readily achieved. Whether a caustic wash is being used through a sprayer or with the aid of a brush, the operator must guard the hands with gloves, wear old clothes and a soft, wide-brimmed hat, which will tend to reduce the probability of the burning spray blowing back into the face. If it is deemed imperative that the younger shoots carrying excellent buds shall be scrubbed, the worker must exercise particular care to proceed in the same direction as the buds point, or many will be dis-

Planting.—This important work will be practically at a standstill from the present time onwards to the end of January, not because it cannot be successfully accomplished at this season, provided the weather is favourable, but because the weather is so uncertain that it is risky to put such tasks in hand. It is always possible on any day that a long spell of frost will set in, and it is most undesirable to have a lot of trees waiting to be planted; therefore it is usually wise to leave the matter severely alone during the period mentioned, the trees meanwhile being heeled in where the roots will remain plump and moist. With the advent of February better climatic conditions are likely to prevail, and the trees can soon be properly placed in their permanent quarters.

THE RED VALERIAN (CENTRANTHUS RUBER) AS A WALL PLANT. IT IS EXCELLENT FOR GROWING IN THIS WAY.

lodged, and thus the remedy will become as bad as the disease. Properly carried out, this winter washing is most beneficial, but to be fully effectual it should be done by all, and not by the few as at present.

Stakes.—When the weather is dry and frosty during the winter, and it is not possible to push on the pruning or to do any land cultivation, a spare hour should be found to test all the stakes that are supporting the trees planted last autumn. Of course, sound, strong supports would have been utilised at the outset, and probably the ends tarred or soaked in paraffin to preserve them, but some will always go, and the more quickly they can be removed and new ones put in the better. When the old stake is out, the fresh one should be driven down into the original hole so as to avoid injury to the roots, and, immediately it is in position, securely attach the stem to it

Pruning.—As long as the weather remains open, and during intervals between hard spells or wet, the pruning should be advanced with all speed. I would urge the desirability, when once the foundation of the trees has been properly formed, of limiting the use of the knife to the removal of crossing or badly placed branches and the reduction of unripe tips of the growths. This means, of course, that the tree will quickly assume its natural habit, and this is precisely what favours the finest crops. The severely restricted shape that has to be adopted in many gardens is by no means conducive to the finest results, and the operations connected with it take up valuable time which might well be more profitably used in other operations in the garden. Obviously these remarks are not applicable to trained trees, but only to those grown as bushes or as standards in the open quarters.

FRUIT-GROWER

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Strawberries in Pots.—If plants were placed in gentle bottom-heat a month ago, the flower-trusses will now be beginning to push forward. As soon as the flowers begin to show colour, the plants should be removed to a shelf quite close to the glass in a temperature of 50° at night. These plants will require increased supplies of water as the season advances, and the foliage should be syringed once or twice daily, according to the weather; but when the flowers are open, no overhead syringing need be given. Any plants which do not promise well may be discarded at once. Continue to place batches of plants in gentle heat as it becomes necessary to keep up the supply.

Early Permanent Vines.—As soon as the buds are sufficiently advanced, these Vines should be carefully tied to the trellis. The night temperature may then be increased to 65° in mild weather, but on cold nights it is better to allow the temperature to drop slightly than to keep it up by hard forcing. Syringe the walls and vacant parts of the bed as it becomes necessary, in order to maintain a moist atmosphere. Disbudding should be carefully attended to as soon as the growth is sufficiently advanced to enable the operator to distinguish which are the most promising shoots.

Midseason Vineries.—Vines in these ought to be pruned and the houses thoroughly cleansed as soon as possible. In pruning these Vines a great deal depends on the variety and the state of them as to how far each spur should be cut back, but where space exists the best practice is to prune to what may safely be regarded as a fruiting bud. With young, healthy Vines two prominent buds are quite sufficient, as this will give the cultivator a choice of which may be the best-placed shoot of the two when the time arrives for disbudding.

Plants Under Glass.

Cyclamens.—Plants which are showing flower will benefit by frequent applications of weak liquid manure. Keep them exposed to the light and admit air whenever the weather permits. If aphid is present on the plants, the house should be carefully fumigated, or the foliage will soon become deformed. Young seedlings in 2½-inch pots must be kept quite close to the roof glass in a temperature of 50° by night, in order to promote clean, healthy growth. As soon as these plants are large enough, they should be potted into 3-inch pots, which must be quite clean and carefully crocked.

Chinese Primulas.—Plants which are in flower should be given a temperature of 55° with a rather dry atmosphere. These are greatly valued at this season for their bright and varied colours, as well as for their pleasant perfume. Young plants for succession should be kept quite near the glass, and if the pots are well furnished with roots, a sprinkling of artificial manure may be given with advantage.

Poinsettias.—The most forward plants should now be gradually hardened by their removal to a drier atmosphere with a temperature of 60°, in order to prepare them for house and church decoration during the Christmas season. Plants for succession may still be grown in a higher temperature, where some stimulant can be applied several times weekly.

The Flower Garden.

Chrysanthemums.—Plants which are stored in cold frames for the purpose of producing cuttings must be examined frequently, and if slugs are troublesome, a sprinkling of soot or lime should be applied to keep them in check.

Pelargoniums.—If space is available, the most forward of bedding Pelargoniums may be potted at once. Plants in 3-inch pots ought to be put in 5-inch pots and placed in a temperature of 50° quite near the roof glass. Verbenas, Lobelia and various plants need to be kept growing all the winter, and where large quantities of Lobelia are required, propagation should be commenced at once, as several batches of cuttings may be secured from plants propagated now.

All decaying foliage should be removed from bedding plants as soon as possible, or much injury may be caused to the stock.

The Hardy Fruit Garden.

Ground Work.—The past month has been favourable for the lifting, root-pruning and removal of all kinds of fruit trees, and this work should be pushed forward as quickly as possible while the weather is open. In all cases where new plantations are to be made, the ground ought to be trenched to the depth of 2 feet, and if stagnant water is present in the soil, a thorough system of drainage must be provided.

Raspberries.—If new plantations are contemplated, no time should be lost in preparing the ground for the plants. This must be trenched and manured, and the plants may be placed in rows 6 feet apart. Later in the season they should be cut to within a few inches of the ground. Established plants ought to be freely thinned and secured to the wires. Lightly fork the ground and give a surface-dressing of farmyard manure.

The Kitchen Garden.

Turnips which are fully matured should be lifted and placed in a cool position. A shed behind a north wall is a very suitable place for them. A great quantity must not be placed together, as they are liable to decay; protection from frost is all that is necessary. Later batches may be left in the ground for some time yet, and when sharp frost sets in, a covering of some light material should be placed over the roots in the bed, where they may be allowed to remain if not too far advanced.

Potatoes in Store should be carefully examined during wet weather, and as this work proceeds the tubers for planting next season ought to be selected and placed in single layers where light and air can reach them. This is a very important matter, as much depends on the selection and care of seed for next season's crop.

Onions in Store should also be examined and all decaying bulbs removed. Ventilation must be freely given. If laid in single layers, they will keep much better than if large quantities are placed together.

French Beans.—If a sowing of French Beans is made now in 7-inch pots, a supply of tender young pods should be available about the middle of February. A temperature of 60° will be necessary. For this sowing The Belfast is one of the best varieties.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Cauliflowers.—Where opportunity exists for growing an early supply of Cauliflowers, a small sowing should now be made of one or other of the early forcing varieties. The seed may be sown in shallow boxes and placed in gentle heat, and as soon as the young plants appear they must be given a position close to the glass. Guard against damping, and prick out into boxes as soon as the young plants are ready.

Asparagus.—To have a supply of this fine vegetable at the commencement of the New Year, a number of clumps should be lifted and placed in the forcing-pit without delay. Care must be taken, however, that the bottom-heat is not too violent, otherwise failure is sure to result. Cover the crowns with about four inches of fine soil, afterwards giving them a thorough soaking of tepid water.

Horse Radish.—These roots may now be dug up and stored among sand or soil for future use. It will be as well to grade the roots at this time, selecting the best for use, and the next size should be stored separately for planting in the spring.

The Flower Garden.

Lily of the Valley.—Beds that have been undisturbed for a number of years will be showing signs of exhaustion, and the resultant flowers small and weak in consequence. The present is a suitable time to make new plantations. The ground for the new beds should be deeply dug or

trenched, at the same time adding some good manure. In planting, select the best crowns; the smaller ones can be planted by themselves in another part of the garden, where, if liberally treated, they will give a useful supply of flowers later. When planting is completed, the bed should receive a top-dressing of such material as that from a spent Mushroom-bed.

Hyacinthus candicans.—Although bulbs of this are generally regarded as perfectly hardy, still, where the soil is inclined to be cold and wet, it will be advisable to lift and store them in sand or soil, where they will get a more complete rest. As, however, the bulbs will be soft, they should not be out of the ground for any lengthened period. They ought to be replanted not later than the beginning of March.

Bedding Plants.—From now till February all bedding plants will require to be carefully attended to, in order to keep them in a healthy condition during the cold and damp weather. In the case of Geraniums little or no water will be required, but, should it be necessary, they must be given a thorough soaking, which will serve them for weeks. Other bedding plants must be attended to similarly. Where only a few stock plants exist, it may be necessary to put these into heat to produce cuttings.

Plants Under Glass.

Begonias.—Winter-flowering Begonias of the Mrs. Heal and elatior type have been seen in much better condition lately, possibly on account of their requirements becoming better known. In the growing season the presence of the tiresome Begonia mite is a source of great annoyance. But possibly the resting period is the most critical stage to get over. When they pass out of flower they should be given a position on a shelf in a warm house and watered very carefully, reducing the supply as they go to rest. At no time, however, should they be allowed to become dust dry.

Lachenalias.—These useful greenhouse bulbs should now claim attention, although many may have been potted up in the autumn. At the outset they ought to be grown in a cool greenhouse, and, until they have made some growth, little or no water should be given. These bulbs are very useful for making up wire baskets to be suspended from the roof; indeed, it would seem to be the most successful way of treating them.

Freesias.—Although these are not very well adapted for forcing—indeed, too much heat is to be avoided—still, some may be hastened into flower by transferring them to a heated pit. A vase or two of flowers about the beginning of the year will be very much appreciated on account of their delicious fragrance.

The Hardy Fruit Garden.

Pruning Apricots.—The pruning of these must proceed on all favourable occasions, bearing in mind that this work should be completed by the end of January. The fruit is produced on the previous year's growths, so that a sufficient number of these should be retained to furnish the wall. Older trees, however, are usually treated on the spur system, and the aim should be to get the spurs back as close to the wall as possible. Avoid wholesale cutting away of these, which will more than likely result in the tree gumming badly.

Nuts.—Although these do not succeed so well in the Northern Counties as they do in the more congenial climate of the South, it is surprising what a useful crop can be secured with a little attention. Although the pruning should not be done much before March, old trees should have the suckers removed now, as well as a few of the older branches where they appear crowded.

Fruit Under Glass.

Young Vines.—Vines that were raised from eyes put in at the beginning of the year may now be cut back to within two eyes from the base. They may still be allowed to rest for a few weeks, and, should they have been well ripened, there will not be much danger of them bleeding to any extent. Should, however, they continue bleeding, the wound must be dressed with styptic.

JOHN HIGHGATE.

Hopetoun Gardens, South Queensferry, N.B.

CULTIVATION AND COLLECTION OF MEDICINAL PLANTS IN ENGLAND.

[The following has been recently published as Leaflet No. 288 by the Board of Agriculture.]

OTHER MEDICINAL PLANTS.

(Continued from page 602.)

CONSIDERABLE demand will occur next year, owing to short supply, for Buckbean leaves, Centaury, Coltsfoot leaves, Feverfew, Figwort, Marshmallow leaves and root, Meadowsweet, Wild Carrot fruits and Yarrow. These include some of the commonest British wild plants, but in the ordinary way few are collected in England except by herbalists, or by herb gatherers on behalf of a few agents for wholesale firms.

The herb collector's calling is a poor one at the best of times, but there is now every prospect of a rich harvest for some time to come. His outfit consists of some old sacks and a "paddle"—a strong iron spud 10 inches long with a cross foot-piece and tough 4-foot ash handle. With this a hard day's work may result in a hundredweight of Dandelion roots being taken to a middleman for forwarding to the manufacturer. The latter will require more henchmen next year, the medicinal plants dealt with below being now in greater request than usual, besides Wild Aconite, Belladonna, Henbane and Stramonium. Farmers and landed proprietors might be asked to allow access to their estates to herb gatherer or local botanist.

Barberry (*Berberis vulgaris*, L.): Bark will be wanted next year. Ordinarily it is worth 40s. per cwt. in the dry state. Home supplies will be insufficient.

Bittersweet (*Solanum Dulcamara*, L.) grows wild in moist, shady situations, and is common in hedges and thickets throughout England. There is only a small demand for the drug, which is prepared from the smooth, two or three year old (about a quarter of an inch thick) branches collected in autumn after the fall of the leaves. The branches should be dried and cut into pieces about half an inch long with a chaff-cutter.

Broom (*Cytisus scoparius*, Link.): The brush-like branches contain most alkaloid in winter, but are also gathered in June for expression of juice.

Buckbean (*Menyanthes trifoliata*, L.): Leaves are generally collected in spring. The plant is a marsh herb distributed throughout Britain.

Burdock (*Arctium Lappa*, L.): The root is still used.

Centaury (*Erythraea Centaurium*, Pers.) is common in this country, and the dry herb will be required next year.

Coltsfoot (*Tussilago Farfara*, L.): The leaves retain some reputation as a household remedy. Plenty are to be had for the trouble of collecting, the plant abounding on poor, stiff soils. The leaves are collected in June or July. The flowers, which appear in spring, are also used to a slight extent, as well as the root.

Elder (*Sambucus nigra*, L.): Flowers will be needed more than usual. They are plentiful, but require quick collection and rapid transit if they are to be used fresh for making Elder flower water. They can be preserved for future distillation by mixing them with 10 per cent. of common salt.

Figwort (*Scrophularia nodosa*, L.) occurs in moist situations throughout England.

Hemlock (*Conium maculatum*, L.) is a biennial growing wild on the banks of streams, along edges of fields or in neglected meadows. It is used chiefly for the expression of Conium juice. It is collected in June from second-year plants.

Horehound (*Marrubium vulgare*, L.) grows wild in this country, but is not common. It might pay to cultivate next year, as it is in steady demand.

Male Fern (*Aspidium Filix-Mas*, Sw.) is one of our commonest indigenous Ferns, growing luxuriantly in moist, sheltered situations. Germany (Harz and Thuringia) supplied all the Male Fern rhizome or extract used in this country, and any rhizome collected in this country will meet a ready demand.

Meadow Saffron (*Colchicum autumnale*, L.) is abundant in moist meadows in some parts of England, and will be much wanted. The corms (or underground "bulbs") should be dug up in July after the leaves have faded, but they are found with difficulty, and are hence usually collected later when in flower.

Meadowsweet (*Spiraea Ulmaria*, L.): More than usual of this herb will need to be gathered.

Mullein (*Verbascum Thapsus*, L.): This biennial plant occurs fairly frequently on roadsides and waste places in Britain. There will be a good enquiry for dry leaves.

Red Poppy (*Papaver Rhæas*, L.): The petals find a steady if limited market. Farmers can arrange to deliver fresh petals to manufacturers. Children can gather the petals, placing them in a linen bag suspended round the neck, leaving both hands for work, and with a little education are a positive help in preventing the spread of this corn-field weed.

Rose petals will be much in demand, Continental supplies being cut off. They usually realise 3s. to 4s. per lb. when dry, but will now be more valuable for a time. Any dark red Rose petals are suitable, and some organisation for collection and drying could be arranged in Rose propagating centres.

Sweet Flag (*Acorus Calamus*, L.) can be found in quantity along the edges of streams and lakes. The dried rhizome will be readily saleable.

Yarrow (*Achillea Millefolium*, L.) is one of the commonest British plants, and the dry flowering tops are utilised.

Squirting Cucumber and *Lactuca virosa* are cultivated in a small way, while Bryony root and Buckthorn berries are among the wild products in very limited demand.

NOTE.—In the ordinary way a few pounds of dried herb are only disposed of with difficulty, buyers requiring hundredweights or none. Next year, however, is likely to be the exception, and such quantities as can be obtained will be saleable. In any case it is best to get into touch with a buyer before commencing to grow or collect medicinal herbs. The drug grower who has special facilities for dealing with these should be approached in the first instance.

THE EDITOR'S TABLE.

Interesting Winter Flowers from Taplow.—Messrs. Barr and Sons of King Street, Covent Garden, send from their Taplow nurseries four interesting and beautiful winter flowers. These are *Iris stylosa* (unguicularis) and its white variety, *Galanthus Elwesii* and *Narcissus Bulbocodium monophyllum*. The Irises are very charming and too well known to need comment, the beautiful blue shade of the type appealing to us more than

the white varieties. Elwes' Snowdrop is also fairly well known now, though it might be grown far more extensively in pots than it is at present. The *Narcissus*, which Messrs. Barr send in a 2½-inch pot, is a perfect gem, the large white hoop, or corona, almost obscuring the narrow and inconspicuous perianth segments. We cannot conceive anything more beautiful for tiny pots at this season. Messrs. Barr write: "We have much pleasure in sending you blooms of *Iris unguicularis* and *I. unguicularis alba*, also a pot each of *Galanthus Elwesii* and *Narcissus Bulbocodium monophyllum*, all from our Taplow nurseries. *Iris unguicularis* and its variety, also the *Galanthus*, have come from the open, the former being cut in bud and opening in our shop window. The *Narcissi* have been grown in a cold frame, where they have been merely protected from heavy rains to prevent damage to the blooms. We are sure you will agree that the pretty little white Hoop-Petticoat makes a most charming pot plant. The *Galanthus* and *Narcissi* were potted in September."

A Beautiful *Cratægus* from Maidstone.—Messrs. G. Bunyard and Co., The Royal Nurseries, Maidstone, send a fruiting shoot of the beautiful Thorn named *Cratægus Carrièrei*. In leaf, flower and fruit *Carrière's* Thorn is one of the most attractive members of a large family. It is a hybrid which originated in France, but what are its parents does not seem very clear. M. Carrière, writing in the early eighties, described it as a seedling from *C. mexicana*; the second parent may be the Cockspur Thorn (*C. Crus-galli*), while some authorities are inclined to the belief that the conspicuous spots on the fruit suggest *C. punctata* as one parent. The glistening white flowers are nearly an inch across, with attractive pink stamens, borne in flattish corymbs towards the end of May and during early June. During autumn, with the lovely tints of the foliage and the orange red fruits, the tree is a beautiful study in red and gold. Its most valuable character has yet to be told, for long after the leaves have fallen the clusters of richly coloured fruits hang on the trees into the New Year. For a Thorn the fruits are large, being three-quarters of an inch in diameter, hanging in clusters of five to ten or more fruits. *Cratægus Carrièrei* forms a round-headed tree 18 feet to 20 feet in height.

THE IDEAL CATALOGUE.

SOME SUGGESTIONS FOR NURSERYMEN AND SEEDSMEN.

GARDENING literature is plentiful enough in these days; but of the many shapes it takes I do not know that, for interest, there is anything to beat a good catalogue; a specialised catalogue for choice; best of all, a *Narcissus* catalogue. The advertising columns of *THE GARDEN* make good reading—amusing, instructive and with more human nature in them than many novels. Still, I like a good catalogue even better; of the *Narcissus* for choice, as I have said. But of the *Narcissus*, as of other things, there are catalogues and catalogues. My own *vade mecum* is the list issued each autumn by a much-respected house with which I have dealt ever so long, and to which all lovers of the flower owe a great debt—X. and Sons, the well-known firm of Pimlico (or somewhere). Theirs is indeed

a model catalogue—in short, like Eclipse, it is easily first, with the rest nowhere. Still, catalogues, like all merely human institutions, are none of them perfect, not even my *vade mecum*. It will have to mend in several details—not many, but a few—before it can be called perfect. For one thing, it uses the word “Daffodil” loosely, without the precision to be expected from such an authority, though that defect is not my subject of quarrel with it on this occasion. The matter in respect of which I now venture to question its wisdom is its way of appraising the merits of certain Daffodils and recommending them to clients; for if you accept the judgment of this catalogue as to the merits of certain flowers, you must come to the conclusion that unless a Daffodil is more or less expensive, it cannot be a flower “of the highest quality”; or, putting it another way, that all cheap Daffodils are necessarily second rate. Now, the most perfect flower conceivable, however dear it may be this year as a seedling, must in a few years become cheap; that is, if it is a good “doer,” and if it is not, whatever its other virtues, it comes in, so far, short of the best. A variety offered this year at £20 per bulb may, a few years hence, be offered at twenty pence. When it becomes cheap, therefore, must its merits be revised, and what is now “highest quality” be labelled second or third quality? And is it credible that among the many varieties of the past fifty years, which were once expensive, but have now become cheap, there are so very few first-class flowers? Yet that is, I think, the general inference that must be drawn from the recommendations made by this catalogue to those who come to it for information or advice.

I have made an analysis of certain of its lists and prices. It may not be an absolutely accurate analysis, but it is as accurate as I can make it, and will be found quite sufficiently so for purposes of argument. The catalogue presents two lists. The first is a list of “New Seedling Daffodils,” while the second, and much the larger, is “A General List of Daffodils,” containing the less recent varieties. The “New Seedling Daffodils” have for myself only a slender interest, being as much beyond my means as the same number of hothouse Orchids. Allowing for “errors and omissions,” the number of such seedlings offered is seventy-four, of which forty-eight—that is, about 64 per cent.—are recommended as “of the highest quality.” The prices of these seedlings, of course, vary; but the average price per bulb is £6 2s. The only comment I desire to make upon this list is that the percentage of “highest quality” is very high, and that, if it may be accepted as correct, the evolution of the *Narcissus* is indeed proceeding “by leaps and bounds.”

Those to whom, as to myself, Providence has sent neither poverty nor riches will naturally concern themselves with the “General List of Daffodils,” since it contains varieties more within range of their purses; but they will find little encouragement in its perusal. In this list, which, be it said, contains the choicest survivals of more than fifty years of sedulous cultivation of the Daffodil by careful hybridisers, you will find comparatively few flowers with the enviable *cachet* of four crosses. Of Daffodils proper—that is, flowers of the trumpet, *incomparabilis*, *Barrii* and *Leedsii* sections—there are, in the general list, 287 varieties, of which thirty-four are recommended as “of the highest quality”; that is, about 12 per cent. of the whole as compared with 64 per cent. of first rates among the seedlings. Still, 12 per cent. of a total of nearly 300 varieties offers a consider-

able choice to the buyer of modest income. Yes; but if you tot up the quotations for the thirty-four first-rate varieties, you will find the average price per bulb to be £1 8s. 6d., a price which, I am afraid, many who love the Daffodil will regard as prohibitive. Glory of Leiden, Van Waveren's Giant, Hamlet, Mme. de Graaff, Victoria, J. B. M. Camm, Sir Watkin and Katherine Spurrell are not catalogued as of the highest quality. And this is a curious thing; for on another page in this same catalogue all these and many other varieties which are pronounced second rate are “recommended for exhibition” to “amateurs competing at spring flower shows.” Surely it is treating amateurs a little cavalierly to advise them to compete at spring shows with second best flowers. It would have been more candid, and perhaps more kind, to tell amateurs that unless they can command varieties at an average price of £1 8s. 6d. they had better leave the field to those who can.

One cannot help speculating what number of crosses the catalogues of a few years hence will give to varieties which now cost ten guineas or twenty guineas per bulb, but which may then be had for as many pence. I can remember the time when Minnie Hume was considered first rate; but now that a dozen of her can be had for sixpence, there is “none so poor to do her honour.” I do not say that Minnie Hume is a flower of the highest quality, or one of the second highest; but if this Daffodil had all the perfections of Challenger (a flower which I do not myself know, but of which it is enough to say that it costs £20 per bulb in the open market), which of us would have the moral courage to call a flower first rate that is retailed at two for a penny? The old stagers among us remember quite well the stir Sir Watkin made when it was discovered wasting its beauty in some obscure Welsh garden, and how wistfully those of us with little to earn watched the annual quotation as it descended shilling by shilling to the level of our means. This flower is as big and handsome now as it was then, but it is no longer (says my authority) in the first rank, though it is in the second, which is more, perhaps, than those who love the flower have a right to expect, seeing that it costs only 1½d. per bulb, or, extra strong, 1½d.

But it is time to point the moral, and the moral is this—that it is a mistake on the part of Messrs X. and Sons to docket flowers “first rate” or “second rate.” Why should I be told that certain of the flowers which give me so much pleasure are only poor trash after all? This kind of appraisal, besides being gratuitous and a trifle officious, is useless, and may be misleading, which is worse. For what makes a Daffodil first or second rate? Is it large size, for which I value maximus, or diminutive size, for which I value minimus? Is it solidity of substance, for which I value Victoria, or a certain delicate flimsiness, for which I value *moschatus*? Is it a sharp contrast of crimson and yellow, as in a fine *Barrii*, or a confection in monochrome like *Duchess of Westminster*? A perianth segment shaped like the blade of Barr's bulb trowel, and intersecting the circumference of its neighbours like a figure in Euclid, or a segment starting like the Great Pyramid, from a broad base and tapering to a point? It is none of these, but such a selection and combination of them as will force you to say, when you look at the flower, “I would have that Daffodil just as it is, and not otherwise.” But someone else may say—and possibly, who knows, he may be a judge who officiates at shows—“I cannot agree with you. For my taste, the perianth segment is not sufficiently like the blade of Barr's bulb trowel,

nor has the flower got the red eye, which means so much to me; indeed, now that I come to look at it, it has no eye at all. Shocking! Besides, look at that refractory twist in its segments (which I like flat and overlapping), to say nothing of the defective stalk, which, to my thinking, is one and three-quarter inches too short.” Exactly, most ably reasoned, O learned judge! To me the flower is “of the highest quality,” because I would not have it changed if this could be done to order; to you it is third rate for excellent reasons of your own.

Let us agree, therefore, to give up the absurd custom of deciding for other people what they are to like best, and let us, in our catalogues, if we really wish to be helpful, state the facts, without exaggeration, in a plain matter-of-fact way, with no superfluity of “precious” adjectives, such as “lovely,” “exquisite,” “noble,” &c. These are all very well for ecstatic amateurs like myself; but in a trade catalogue the use of such fine phrases is mere puffery to which no firm should condescend. What we want in a trade catalogue is a bald inventory (the balder the better) of the points of the flower; and the points about which I should myself desire information, if I meditated the purchase of a new bulb, are these: Classification of the variety; colour, texture, shape and size of bloom; proportion of parts (e.g., crown relatively to perianth); stalk; foliage; vigour of constitution; reproductiveness (that is, increase by offsets, receptiveness of stigma and fecundity of pollen); suitability for specific purposes (e.g., pot culture, massing, growing in grass, &c.). This looks a large order, but it is not really so formidable as it looks. When bulb merchants in their catalogues supply these particulars (and perhaps a few more which other buyers may suggest), we shall no longer require to be told whether a variety is “of the highest quality,” and we shall be coming at last within measurable distance of the perfect catalogue, which may I live to see.

SOMERSET.

THE MOUNT ETNA GENISTA.

DURING the scorching hot days of July and August, when many flowering shrubs need a deal of coaxing to keep them alive, the graceful Mount Etna Genista (*G. ætnensis*) gives us showers of its golden blossoms. It is an ideal shrub for hot, sandy soil, where many other kinds will not thrive, but it also seems at home in other and widely diverse situations. Last autumn I noticed some wonderful bushes of it overhanging a placid pool in a Thames Valley garden, and a beautiful picture they made, the reflection of the slender stems and golden blossoms in the water adding not a little to the charm of the surroundings. Although in a young state the shoots are sparsely clothed with soft, silky foliage, in older specimens they are quite devoid of leaves. This, however, is not very noticeable, as the slender, delicate green shoots make excellent substitutes. In common with others of the genera, and also its near ally the *Cytisus*, this Genista is not easily established, and for that reason young plants in pots should, if possible, be purchased. When full grown a good plant may be anything from 12 feet to 18 feet in height, and I know of few shrubs that are more attractive during autumn, and none that is better adapted for growing in hot, dry situations. In addition to the rich golden colour of the small, Pea-shaped flowers, they emit a rather strong yet pleasant fragrance, a feature that should commend the plant to many.

TROJAN.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PHEASANT'S-EYE NARCISSUS (A. B. C., Lancs).—It is not clear from this name to which variety of *Narcissus Poeticus* you refer. The double form is prone to so-called "blindness," and the May-flowering *Poeticus*—that often referred to as "Pheasant's-eye"—is not free flowering under certain conditions of shade or in dry soils. The variety *ornatus* requires good cultivation, though it rarely fails when the bulbs are of the right size. The other "Daffodils" which now flower very badly, and have been in their present situation nine years and are very thick, are obviously overcrowded and require dividing, replanting and fresh soil. You cannot do this now with advantage, and if done would only further weaken the bulbs and delay their ultimate recovery. Such work should be done in July, and as that time is far distant, we suggest you write us in early June next and we will tell you what is best to do. Meanwhile, assist growth by a mulch of manure and by frequent watering with liquid manure in spring. If stable manure is not available, apply Clay's Fertilizer and Wakeley's Hop Manure to the soil.

ROSE GARDEN.

HÆMANTHUS AND ROSE (E. W.).—The *Hæmanthus* bulbs should be potted in a mixture of loam, leaf-mould and sand, and placed in the warmest part of the greenhouse. Until growth commences, only sufficient water should be given to keep the soil slightly moist. You say nothing about the treatment your plants have received; therefore we cannot decide whether yours have been rightly treated or not. If your bulbs were freshly imported from South Africa, we see nothing wrong in their behaving as they have done, for when bulbs are sent from any part of the world where the seasons are the reverse of ours, it takes some time for them to fall into line with those grown in this country. They should flower in the summer, but freshly imported bulbs are as erratic in this respect as in their time of starting into growth. With regard to *Rose Juliet*, it is the reverse of being a poor grower, as its strong, upright shoots are very vigorous. It certainly does not flower with the same freedom as many others do. As the plant is such a strong grower, the planting, or the conditions under which it is placed, must be at fault, providing always that the plant referred to was a good, well-rooted one. Many *Roses* are advertised so cheaply that it is impossible to produce satisfactory ones at the price; hence it is far better to obtain plants from a reliable source, and, above all, plant them with as little delay as possible, providing the ground is in a suitable state; if not, lay the roots in soil at once till the place is prepared for them.

TREES AND SHRUBS.

PRUNING A SUMACH (G. H. N.).—The best time to cut your *Sumach* back is February. It may be pruned

fairly severely, but all wounds should be coated with tar afterwards. The plant will probably produce more young branches than are actually required to form a well-furnished specimen. In that case some should be removed when a few inches long.

THE GREENHOUSE.

FREESIAS FOR INSPECTION (G. B.).—We see little amiss with your *Freesias* except that the edges of one or two leaves have got slightly yellow, due, in all probability, either to a little over-watering or to the exposure of the plants to frost for a time. The curiously swollen roots are quite normal, and are formed by almost all corms for special purposes.

PLANT FOR IDENTIFICATION (A. E. S.).—The name of the plant from which the leaf was taken is *Grevillea robusta*, a native of Australia. From its deeply cut, Fern-like foliage it is much grown for various decorative purposes. It is a very good room plant, but does not possess any special gas-resisting qualities. With the darker nights now upon us, you, of course, burn more gas, and consequently the conditions are not so favourable for plant-life as they were when the days were lighter. The smoke-laden fogs that are so often experienced in the neighbourhood of London cause the leaves of this *Grevillea* to drop in a wholesale manner and leave the plant quite bare. It is quite possible that the young shoots referred to by you as being just pushed out will continue to grow, and in spring the plant will be again furnished with its handsome leaves. In its native country this *Grevillea* forms a large shrub, so that it is not likely to flower in a small state like yours; indeed, it rarely blooms in this country. In the London parks, *Grevillea robusta* may frequently be seen in summer employed as a dot plant in beds of lower-growing subjects. We advise you to keep your plant in as light a position as possible, where it is quite safe from frost. It requires a moderate quantity of water during the winter; that is to say, enough to keep the soil fairly moist, but not saturated.

FRUIT GARDEN.

FRUIT GARDEN (A. B. C., Lancs).—You do not say whether the area is laid out in any form or merely a vacant plot between walls. If the latter, and assuming that the walls are not less than 8 feet high—they would be better at 10 feet or 12 feet—we should advise 8-feet-wide borders adjacent thereto for the accommodation of bush fruits in front of the wall trees. In larger areas bush fruits frequently intersect the rows of pyramid or standard trees, whichever is favoured by the planter, and in this way provide a certain revenue till the others come into bearing. In your small area we think it best to keep them apart and grow Strawberries or Potatoes between the larger trees for the first year or two. You tell us nothing of the purport of the proposed planting, and unless the fruit is intended for home consumption, i.e., private use, we say at once that you are attempting too much in the area named. Moreover, it is important to us to know whether for private or commercial use, because for the former a long season or succession of fruits is of the highest importance, and which is less so when fruits are sent to market. In the absence of such particulars, and because of the variety required, we imagine the fruits are intended for home use, and our reply is based thereon, though you finally enquire whether Damsons would pay to plant. In so small a space we think not. Of dessert Apples, Devonshire Quarrenden, James Grieve, King of Pippins, Cox's Orange Pippin, Braddick's Nonpareil and Lord Burghley; culinary, Frogmore Prolific, Stirling Castle, Lane's Prince Albert, Bismarck, Bramley's Seedling and Newton Wonder. Pyramid trees are recommended: Pears, Doyenné d'Été, Williams' Bon Chrétien, Beurré Superfin, Marie Louise, Doyenné du Comice and Josephine de Malines, all dessert sorts. May be planted as pyramids, or grown as single cordons on walls. Stewing Pears, Catillac, Durondeau, General Todleben and Vicar of Winkfield. Plums, dessert, Coe's Golden Drop, Early Transparent Gage, Jefferson, Kirke's Purple Gage and Reine Claude de Bayay; kitchen Plums, Czar, Dymond, Early Prolific, Grand Duke, Pond's Seedling and Victoria. Grow dessert sorts on south and east walls. Cherries, Belle d'Orléans, Black Eagle, Elton, Early Rivers, Black Tartarian and Kentish Bigarreau. Red Currants, Fay's Prolific and Ruby Castle; Black, Boskoop Giant, Lee's Prolific and Baldwin's; White, White Versailles. Gooseberries, dessert, Langley Gage, Leader, Golden Gem, Red Warrington and Whinham's Industry. Raspberries, Perfection, Superlative, Yellow Superlative and November Abundance. Important cultural items are that the land should be deeply trenched and burnt earth freely, or lime at the rate of two bushels per rod, added. For stone fruits, it should be remembered that lime is essential, and in preparing a 2-feet-wide trench, chalk or lime should be freely incorporated with the staple soil.

SOIL FOR FRUIT TREES (H. C. F.).—If your soil is, as is very probable, deficient in lime, we think it would be a good thing to give it a dressing of powdered chalk at the rate of about three tons to the acre. Potash salts you will find too expensive this season to use, but you may safely use superphosphate if you have added the chalk, and it would probably improve the keeping qualities of the fruit. It should be added that many varieties of Pears are better for being picked a little while before they are actually ripe.

ARRANGEMENT FOR FRUIT TREES IN NEW ORCHARD (Fruit Trees).—The arrangement suggested is so good that we can find no fault with it. We presume the orchard is intended for the home supply of fruit, and not for sale. The distance apart to plant is quite correct. Apple trees do not assume the pyramidal form naturally like the Pear does, and we think you would do better with all bushes and no pyramids. These should be grafted on

the dwarfing English Paradise stock and the standards on the free or Crab stock. Pear trees for espaliers should be worked on the Quince stock. We need scarcely remind you that fruit trees do badly when grass is permitted to grow over their roots, and especially is this the case when the trees are young.

KITCHEN GARDEN.

CARROTS FOR INSPECTION (Weaver).—Your Carrots appear to have been attacked by the Carrot fly grub, and as the parents which lay the eggs fly readily, soil dressings are of little avail against them as a rule. The trouble is lessened by keeping the soil about the roots of the Carrots firm, by destroying the thinnings immediately instead of leaving them on the soil, and by sprinkling sand moistened with paraffin along the rows about the time the thinning is done.

MISCELLANEOUS.

NAME OF FRUIT.—H. Ingram.—Hormead Pearmain.

SOCIETIES.

THE NATIONAL ROSE SOCIETY.

ANNUAL GENERAL MEETING.

The annual general meeting of the National Rose Society was held in the Connaught Rooms, Kingsway, London, W.C., on Thursday, the 10th inst., the president, Mr. C. E. Shea, presiding over a large gathering. The report and financial statement submitted show that, in spite of the war, the society has had a good year and that its finances are sound. There is now about £2,000 in the reserve fund, £500 being added in 1913, leaving a working balance at the end of that year of £474 15s. 11d. For the year ending 1914, after paying all expenses, the society has a balance in hand of £704 18s. 3d., a very satisfactory condition considering everything. Mr. Shea, in proposing the adoption of the report and financial statement, said that there was not the slightest need for them to be depressed. Naturally, they had lost some members, many of whom had stated their intention of rejoining as soon as the war is over, but during the year they had made a net increase in membership of 222, the total number of members now being 6,257. He thought that professional Rose-growers would probably benefit soon by the war, as a great many people were making a lot of money out of various contracts, and they would soon want to plant Roses. Some discussion had arisen in the past concerning the abandonment of the autumn show, but the Council had no option but to take that course. He thought the one sad feature of the report was the paragraph referring to the retirement of Mr. Mawley from the hon. secretaryship, but was glad to know that they would not lose his services entirely as he was to be their president for the next two years.

Mr. G. Paul, V.M.H., in seconding, said that he could heartily endorse Mr. Shea's remarks, especially those referring to Mr. Mawley. As a trade grower he felt very grateful, and he was sure others did also, to the private growers who had supported them during the present crisis by giving orders as liberally as they could.

The Rev. J. H. Pemberton stated that before the report was adopted he would like to point out that the society's publications did not come before the whole of the members of the Council for approval; they were the work of the publications committee. In the recently issued "Hints on Planting Roses" there were several things that he wished to dissociate himself with, especially the statements relating to the Roses raised by M. Pernet-Ducher. He would also like to see the last part of the paragraph in the report relating to the provincial show deleted, and moved that this be done. This was unanimously carried.

The proposed alteration of rules, as sent out to members, was the next business. Mr. E. J. Holland proposed that the first five paragraphs of suggested alterations as circulated be adopted, this being seconded by Mr. Cecil Cant. This raised a protest from a member, whose name we were unable to ascertain; but the protest, which took considerable time on the part of its mover to put before the meeting, was not very clear. Mr. Holland's motion was carried. The remaining paragraphs of alterations were proposed by Dr. Williams, and duly seconded and carried. Dr. Williams also moved the alteration of by-law No. 1. The deletion suggested, he pointed out, would enable the Council to have a free hand in fixing the date of the metropolitan exhibition. Mr. Dennison spoke against this, but after some discussion the proposal was carried. A vote of thanks to the officers and Council for 1914 was proposed by the Rev. H. S. Arkwright, and seconded by Mr. F. W. Harvey.

The next item on the agenda was the special vote of thanks to Mr. Mawley for his services as hon. secretary. In moving this the president referred in glowing terms to his services to the society, these remarks being seconded by the hon. treasurer, Mr. G. W. Cook, and endorsed by Mr. George Paul, V.M.H. On page 605 we give Mr. Mawley's portrait, and also some details of his work in connection with the society. This special vote of thanks was carried unanimously and with acclamation.

The result of the ballot was next announced, all the names sent out to members standing with the exception of Mr. T. G. W. Henslow and Mr. H. J. Spooner, the former being a newly nominated member for the Council, and the latter an old member of the Council. The president now is Mr. E. Mawley, V.M.H.; deputy-president, Mr. E. J. Holland; and the hon. secretaries, Mr. H. R. Darlington and Mr. Courtney Page. New members of

the Council are the Rev. H. S. Arkwright, Messrs. A. R. Bide, W. J. Grant, F. W. Harvey, B. Peyman and A. E. Prothero.

The induction of Mr. Mawley as the new president was the occasion of a remarkable scene, unparalleled, we think, in the annals of the society, the whole of the members rising and cheering enthusiastically, finally joining in singing heartily "For he's a jolly good fellow." Mr. Mawley suitably replied, and then stated that his first duty as president was the very pleasant one of handing to Mr. Shea the Dean Hole Memorial Medal as some slight recognition of his services in the interests of the society. A portrait of Mr. Shea will be found on page 603.

The conversazione held at the conclusion of the annual meeting was well attended, and was the most comfortable and successful of its kind the society has ever arranged. The artists were excellent, and the tables beautifully decorated with Roses by Mr. R. F. Felton. The society's lantern slides of Roses, prepared and shown by Mr. Wettern and explained by Mr. E. J. Holland, were very fine indeed, and the coloured scenes transported the audience to the gardens of July, so realistically were the Roses depicted.

EAST ANGLIAN HORTICULTURAL CLUB.

THE annual meeting was held on Wednesday, December 9, at Norwich, Mr. John Clayton presiding. The report, presented by Mr. W. L. Wallis, secretary, stated at the outset that some twenty members had enrolled themselves in His Majesty's Forces, and that £4 had been subscribed to the National Relief Fund. The membership numbers 365. The financial position is sound, there being a balance in hand of £127 7s. 8d. The educational work of the club, carried out by means of exhibitions, papers, lectures and debates, has been most successful during the year. Mr. J. D. Cockerell, gardener to Mr. G. E. White, Eaton, was the champion exhibitor of the year. It was incidentally mentioned that Mr. Cockerell is now in Kitchener's Army. Mr. W. Shoesmith becomes the possessor of the Harmer Silver Challenge Cup, having won it three years. Thanks are accorded to the donors of special prizes and to those who had made special exhibition displays during the year, special mention being accorded to Messrs. Daniels Brothers, Limited; Hobbies, Limited; and Mr. Frank Neave. The outing to Kew Gardens in the summer and a presentation of a silver flower vase to Mr. Herbert Perry are alluded to. In conclusion, the report thanks Mr. John H. Willis for his interesting monthly weather reports, the local and gardening Press for their reports of meetings, and the office-bearers for their services. The election of officers followed, at the outset of which Mr. H. Perry moved that the club should suspend the rule calling upon the president and vice-president to be changed, urging that it would be wise to retain the services of Mr. John Clayton and Mr. T. Notley in these respective positions. This suggestion was unanimously agreed to. All the other officers were re-elected, a special tribute being paid to the energetic secretary, Mr. W. L. Wallis, for his untiring devotion to his office in spite of the fact that his health has not been at its best. Mr. George Henley, Earlham Hall Gardens, Norwich, was added to the committee. The exhibition tables presented a bright appearance, Begonias and Primulas predominating in the flower section. Apples were good, especially the dishes of Cox's Orange Pippin. Mr. W. Shoesmith staged some extra good Grapes, both black and white.

HIGHCLIFFE GARDENERS' ASSOCIATION.

ON December 7 there was a good attendance of members when Mr. C. J. Gleed, Staff Teacher, Hampshire County Council, gave an interesting and valuable lecture on "Insect Pests." The lecturer dealt with green and black aphides first, as they were such common pests and caused so much trouble. The most effectual way to get rid of them was to smother them wholesale, and to this end, he said, fumigation, vaporising and syringing with soft soap and quassia, and also with a paraffin emulsion, should be carried out. A good emulsion could be made that would keep well for a year in bottles. Twelve ounces of soft soap should be placed in a gallon of water, adding one gallon of paraffin; this mixture should be gently boiled and well churned up to bring it to a thick creamy emulsion; afterwards it should be once more gently boiled, when it would be in a fit state to store. Use one part of the emulsion to twenty parts of clear water on ordinary plants, and one part to twenty-five parts on tender foliage when syringing. This emulsion was also recommended for killing caterpillars on Currant bushes. Lead arsenate was advised as a cure for the ravages of the Codlin moth if the solution was sprayed on directly the flowers had fallen, as then the grubs were poisoned as soon as hatched. Mr. Gleed recommended soil fumigants in the case of wireworm-infested land. The more porous the land was, the better the result of the fumigants. All click beetles found in rubbish should be destroyed, as well as traps set for catching the wireworms in the soil. Leather-jackets, grubs of the daddy-long-legs, could be got rid of, to a great extent, by surface stirring of the soil, as then the birds would find and eat them. Sodium cyanide was advised for killing mealy bug, white fly and red spider in glass structures, but owing to the great danger attendant on its use, Mr. Gleed said much care should be exercised in using it and in the opening of doors and ventilators from the outside for some time before anyone was allowed to enter the house. He also dealt with the mites on Black Currants and with the uses of sulphur as a remedy for red spider and other mites. A discussion followed, and the lecturer replied clearly to many questions put to him.

TWICKENHAM HORTICULTURAL AND MUTUAL IMPROVEMENT ASSOCIATION.

AT the last monthly meeting of this society, Mr. W. E. Reeves in the chair, Mr. E. Montague, The Gardens,

Grey Court, Ham, gave a very instructive lecture entitled "Hints to Allotment Holders on the Cultivation of Vegetables." The lecturer has practical qualifications for dealing with the cultivation of vegetables. For two years in succession he has won the valuable challenge cup for the best collection of vegetables offered by this society, always against strong competition. The lecturer in his opening remarks pointed out the necessity of deep cultivation if first-class vegetables are desired. Another important point often overlooked was the selection of good tools to do the work properly, which helped to do the work much more expeditiously than was the case with indifferent tools. The lecturer then gave a list of vegetables most suitable for cottage garden and allotment holders, dealing with each variety separately, and gave some useful hints on sowing the seed, thinning, rotation of crops, the use of various manures, and the treatment of the various insect and fungoid pests, which altogether proved a very interesting and instructive lecture, not only to allotment holders, but to professional gardeners present. Mr. Montague brought an excellent collection of vegetables worthy of a place on any exhibition table. These, by kind permission of his employer, Colonel Biddulph, were given to St. John's Hospital, Twickenham. A very hearty vote of thanks was accorded Mr. Montague for his very able lecture.

DUMFRIES AND GALLOWAY GARDENERS' ASSOCIATION.

AT the fortnightly meeting of this association, held in the Wesley Hall, Dumfries, on the evening of December 5, the subject was "Flowering Trees." Mr. S. Arnott, chairman, presided over a good attendance, who listened to the lecture—which was given by Mr. D. Hunter of Messrs. Barr and Hunter, Dumfries—with close attention. Mr. Hunter gave an admirable lecture, referring to the importance of the flowering tree in the garden and grounds, and to its comparative neglect in small gardens. He gave an excellent survey of the leading flowering trees, pointing out the best genera, with their species and varieties, and giving valuable details regarding their merits and peculiarities. In the course of the discussion which followed, the thanks of the members to Mr. Hunter were expressed. The chairman, Mr. W. Hutchinson, Mr. J. Henderson, Mr. C. G. Murray, Mr. J. Jeffrey and others took part in the discussion, and Mr. Hunter replied to the points raised in a succinct manner.

WARGRAVE AND DISTRICT GARDENERS' ASSOCIATION.

THERE was a very good gathering of members on December 2, when the hon. secretary, Mr. H. Coleby, gave his second lecture on "Soils." He first briefly recalled the chief points of the lecture given last session, and then dealt with the mechanical analysis of the soil, showing how to test it for humus, carbonate of lime, sand and clay, and the method of working out the percentage of each. The experiments were watched with great attention, and many questions respecting the procedure were asked after the lecture. A good discussion was also maintained and much other useful information brought out, and a hearty vote of thanks was carried with acclamation to the lecturer at the close. Mr. T. Tunbridge of The Three Elms Gardens, Remenham, exhibited a good lot of single Chrysanthemums and was awarded a cultural certificate by the judges. Three new members were elected.

Improvements at Duthie Park, Aberdeen.—

The newly appointed superintendent, Mr. W. B. Clark, is effecting a number of improvements in this important park. Chief among these are internal alterations to the Palm House, where many of the plants are already showing signs of the improved conditions under which they are growing. Outdoors, also, considerable alterations are in progress, and next summer it is hoped that these will be highly appreciated by the public.

Vegetables and Fruit for the Navy.—At a meeting of the committee of the Dumfries and District Horticultural Society, held in Dumfries on December 5, Mr. S. Arnott in the chair, it was resolved to support the scheme for the provision of fresh vegetables, &c., for the Navy, embodied in a letter received from Lord Charles Beresford in connection with the Vegetable Products Committee. The proposal was heartily and unanimously supported, and a committee was appointed to organise the movement in the district and to appeal for supplies.

Balloch Park, Loch Lomond.—The Glasgow Town Council, at a meeting on December 8, approved of the proposal in their draft provisional order to purchase an estate on the shores of Loch Lomond, near Balloch, as a public park. The cost of £30,000 is to be paid from the Common Good, and the park will be maintained from the

public rates of the city. Although the property of the city of Glasgow, and secured through the patriotic action of the Council, the new park will be truly a national one, securing for the public access to one of the most beautiful of Scottish lakes.

Henry J. Clayton Memorial.—In March last, following upon the deeply lamented death of Mr. Henry J. Clayton, who was for so many years gardener at Grimston Park, Yorks, you were so kind as to permit me the hospitality of your columns to formulate a proposal that his many friends in the horticultural world should unite in raising a memorial to his memory in connection with the Royal Gardeners' Orphan Fund, of which he was one of the original promoters and subsequently one of its most strenuous supporters. I now beg you to kindly allow me to state that as a result of that appeal I have had the pleasure of handing over to the treasurer of the Fund the sum of £50, together with a list of the contributors, who I am sure will be gratified to know that a permanent memorial to Mr. Clayton's worth as a gardener and as a friend, and of his good work in connection with the Fund, is thus assured for all time. I would wish also to be permitted to express my hearty thanks to all who have thus helped to perpetuate the memory of our old friend in the way that I know would be most dear to his heart.—T. TURTON, *The Castle Gardens, Sherborne, Dorset.*

TRADE NOTE.

BOILERS FOR GREENHOUSES.

NOW that the cold, damp weather is with us, it is necessary to keep a steady, warm temperature in our greenhouses. To do this it is necessary that the boiler should be thoroughly reliable and economical, otherwise all our labour in other directions is lost. Those who need new boilers for greenhouse or conservatory should write for the excellent catalogue just issued by Messrs. Pearce and Co., 644, Holloway Road, London, N. This catalogue is well compiled and fully illustrated, and in its pages amateurs will find a good deal of very interesting information. Messrs. Pearce will be pleased to send a copy post free to any of our readers who care to write for it. In spite of the war, they inform us that they have made no advance in the usual prices charged for their boilers.

CATALOGUES RECEIVED.

H. J. Jones' Nurseries, Limited, Ryecroft, Hither Green Lewisham: New Chrysanthemums.
Seadons, Limited, St. Albans: Sweet Peas.
Messrs. W. Drummond and Sons, Limited, 57 and 58, Dawson Street, Dublin: Fruit Trees, Shrubs, Roses, &c.
Mr. T. H. Dipnall, near Hadleigh, Suffolk: Sweet Peas.
Messrs. Little and Ballantyne, Carlisle: Trees and Shrubs.
Messrs. William Watson and Sons, Limited, Clontarf Nurseries, Dublin: Fruit Trees, Roses and Shrubs.

SITUATIONS WANTED.

Our charge for advertisements under the above heading is 1/6 for 26 words, and 6d. per line after, consisting of eight words to the line. Press day Friday.

LADY requires post after Christmas, as Assistant in garden or poultry; two years' training.—Apply "S," Box 4, c/o THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.

"BUCKS' TRESCO" TOMATO

Award of Merit and Medal, Birmingham Floral Fete, 1914.

Quite distinct. Powerful testimonials.

Most Prolific. Seven-Pound Trusses.

Re-selected strain, in Raisers' Sealed Packets:—50 seeds, 1/-; 150, 2/6; 350, 5/-; 500, 7/-; 1,000, 12/6. **SOW NOW.**

Ordinary strain, double above quantities, same price. Strong plants now ready, 5/- doz.

BUCKS' Britannia Road, IPSWICH.

THE GARDEN.

No. 2249.—Vol. LXXVIII.

DECEMBER 26, 1914.

NOTES OF THE WEEK.

To Our Readers.—By the time this issue is in the hands of our readers, Christmas will be very near and a memorable year swiftly drawing to its close. Our outdoor gardens, though hushed and still, are not devoid of interest, as we have tried to point out on another page, even though the earth be scarred by wintry blasts and bare of the glories of summer. With nearly the whole of Europe in arms, the stereotyped Christmas greetings this year possess less meaning than ever. Our thoughts naturally turn to Belgium, a country that possesses peculiar interest for horticulturists in the United Kingdom. So surely as our gardens, now in their winter bareness and swept by cruel winds and frosts, will awaken to a greater glory, so shall the fair land of Belgium rise from its tribulation greater, nobler and more beautiful. When the time for restitution comes, horticulturists will not be slow to render to our distressed Allies the material assistance that will be so urgently required. To our readers the world over, and especially to those who from time to time send us letters of appreciation, we tender our thanks for support so loyally given.

General Index to this Volume.

The present issue completes Vol. LXXVIII., and we are therefore presenting a general index, together with a title-page and frontispiece, suitable for binding the whole of the issue published during 1914. Next week we shall publish our Special New Year Number, which will contain numerous articles by the best recognised authorities in this country. Of more than ordinary interest will be the first of a series of articles by Sir Herbert Maxwell, Bart., on "Hardy Lilies." As there is always a large demand for the New Year issue, we advise our readers to place their orders well in advance.

Mr. Vernon T. Hill joins the Army.—The many friends of Mr. Vernon T. Hill of the Mendip Nurseries, Bristol, will be interested to learn that he has received a commission as captain in the 12th King's Royal Rifles. Mr. Hill is well known among Sweet Pea enthusiasts, having been a hard-working member of the committee of the National Sweet Pea Society for some years. He also invented the "V.T.H." Slug Trap, which has proved such a boon to gardeners.

A Useful Berried Shrub.—At this season any berry-bearing plant is very useful for decorations, either in the garden or the house. One of the most useful for this purpose is the common Butcher's Broom (*Ruscus aculeatus*), as its large red berries are very conspicuous and are excellent for decorations, particularly when berried Holly is not very plentiful. It will thrive in almost any position, and is excellent for planting under trees. Being dioecious, it is essential that one or two male plants should be mixed with the berry-bearing ones.

The Winter Jasmine.—During the summer months, when our gardens are filled with the flowers of many other beautiful shrubs, the yellow

tion, and at others of as many weeks. Recently we have had enquiries from numerous readers for information about protecting Roses from such frost. With established bushes an ordinary winter does little or any harm, but those newly planted are liable to suffer badly. We know of no better method of protecting them than heaping stale coal ashes, or, failing these, porous or sandy soil, well up between the growths. This prevents the lower buds, on which we must rely for growth next year, being damaged, and is far better than straw, manure, or other litter. With standards, some sprays of Yew or other evergreen tied among the branches usually afford sufficient protection, and straw is quite permissible, as it does not remain sodden for any dangerous length of time.

POLEMONIUM RICHARDSONII ALBA, A CHARMING PLANT FOR THE ROCK GARDEN.

Polemonium richardsonii

alba.—Botanically, *Polemonium richardsonii* is referred to *P. humile*, though the plants that are met with in cultivation under these names are distinct enough for all garden purposes. For example, we have never seen *P. richardsonii* so consistently dwarf growing as *P. humile*, or the latter so consistently tall growing as the former. *P. richardsonii* is usually 1½ feet high, a third of this being the average height of the other plant named. In this connection it is interesting to note that "Don" in his "Dictionary of Gardening," while making no allusion to *P. humile*, refers to *P. richardsonii* as a 6-inch-high plant. Hence, probably, there is either confusion among the species or, what is equally likely, a few genera-

tions of seedling-raising have quite outstripped the original in vigour and in other ways. That named above, the subject of the illustration on this page, has pure white flowers, the typical kind having pale blue flowers with yellowish tube. Pleasing in flower and ornamental in the pinnate character of their leaves, they are worthy subjects for the rock garden or front places in the select herbaceous border. Seeds are produced with some freedom, and if sown as soon as ripe, the seedlings soon make nice flowering tufts. The plants also lend themselves to increase by division of the tufts, an operation best performed with the return of growth in early spring.

Protecting Newly Planted Roses.—Usually when Christmas is over we get a spell of severe frost, sometimes of only two or three days' dura-

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Banksian Roses.—We have a Yellow Banksian Rose on the east side of this house that has hitherto flowered well every year; it is only pruned regularly.—G. MOON, *Penyvoel House, Llanymynech, S.O., Montgomeryshire.*

Cistus ladaniferus.—I am sending you a photograph of *Cistus ladaniferus*, to show what this plant can do in difficult situations. The plant, one of a hedge, was three years old at the time the photograph was taken in 1913, and has now grown nearly twice the size. It is planted in heavy,

and I mention it in the hope that some disappointed gardener may find *Gentiana verna* less difficult to grow in future.—MARY GRIFFITHS, *Oakfield, Charlton Kings, Gloucestershire.*

Weeds as Foliage.—"Anne," said my maiden aunt, severely, as she seated herself at breakfast, "I believe you like weeds." Outwardly bold but inwardly quaking, I replied, "I do like some." "Humph! I thought you must. I've just walked round your garden, and it's full of them." Now, this was exaggeration and a gross libel on my old gardener (nicknamed *Too-Tidy*). But I have observed that folks who go walking before breakfast are often somewhat self-righteous and censorious at that meal. Now I will explain, for the benefit of other poor amateurs who, like

ground and cover over the crowns with a few inches of soil or ashes. When winters are mild they push their growth through the soil or ashes, and are cut back again when frost is severe; but we find they are not at all injured even if cut back several times during the winter and early spring. The principal varieties grown at Burford are *C. Powellii*, *C. Powellii alba* and *C. Moorei* (or *makoyanum*), but *C. Powellii alba* is the finest of them.—WILLIAM BAIN, *Burford Gardens, Dorking.*

—"Enquirer's" difficulties, referred to on page 594 of your issue of December 12, in reconciling the various catalogue instructions for planting *Crinum Powellii*, probably arise from the tapering character of the bulb, which in developed plants measures from 1½ feet to 2½ feet from base to tip. With an 18-inch bulb two of the apparently antagonistic instructions become identical, as to plant "12 inches deep" is to leave "one-third of the bulb above the surface." The point in deep planting is winter protection, but it is, of course, equally necessary that the ground should have been well worked, manured and drained for a further 2 feet. We have just dug up an old-established clump from the north side of a low greenhouse wall, which has always flowered well with the roots 1 foot beneath the surface, and proved hardy, although a south exposure is much preferable. The recent editions of "The English Flower Garden" no longer repeat the instructions quoted by "Enquirer," but are content with the remark that "the bulbs should be so deeply planted as to show only the upper part of the neck."—R. WALLACE AND CO.

—In response to "Enquirer's" request, my bulbs were planted 6 inches to 8 inches deep. They have been for twenty years or more in the same spot, and produce annually a good display. *Crinum Powellii alba* has not been planted nearly as long. It was planted in the same manner, and its blooms are as abundant as beautiful. Certainly "doctors differ and patients—or plants—die," but, if surface planting be attempted, winter protection is all the more necessary. Even with deep planting mine are given a coating of dead Beech leaves round their stems, then some coarse cinders, and over all some prunings of evergreen shrubs. The necks of the bulbs, often nearly a foot long, require this protection so as not to weaken the bulbs. I do not believe any *Crinum* has a complete rest; only a much retarded or arrested growth in British gardens.—J. HILL POE, D.L. (Captain).

Araucaria imbricata as Firewood.—I notice, in reply to "Mrs. F. E. R.," on page 592, issue December 5, you do not recommend the timber of *Araucaria imbricata* for firewood. For my part I cannot understand why anyone grows the Monkey Puzzle except in parks or park-like grounds. One sees this tree planted bountifully in villa gardens, and I never behold one but I think that it has been placed there by a speculative builder, or by one who has no knowledge of gardening or lacks good taste. It is a tree which exhausts the soil it grows in as much as anything I am cognisant of, and after having prospered at the expense of any neighbours, rain seldom penetrates its branches when the tree is some twenty-five years old. At best it is an ugly thing, especially after it loses its lower boughs, as it generally does at an early date if planted near a town. It is also a danger to those who unluckily come into contact with it. While the boughs are highly inflammable,

A PLANT OF *CISTUS LADANIFERUS* IN A READER'S GARDEN. THIS IS A CHARMING HARDY SHRUB.

stony, clay soil, with no manure or lighter soil added, and the only protection we give is in the hardest part of the winter, when a wind-screen is placed on the north side. This is a very exposed position here. I may add that all the *Cistus*es do well here in the same soil, and I think it a great pity they are not more largely grown, as the length of time they flower compares very favourably with other shrubs.—B. LEACH, *Boidier, Headley, Epsom.* [The *Cistus*es also thrive in poor, sandy soil.—ED.]

How to Grow *Gentiana verna*.—In connection with the Royal Horticultural Society's Show at Chelsea in 1913, I saw a suggestion that *Gentiana verna* should be grown in turf. As I had lost plants for some years, I jumped at the idea and ordered a new stock. Having by me dried specimens from Switzerland fully 4 inches high, I thought I might venture to put the small Irish form in a rough turf edging, where the rock garden slopes down to the bog garden. The grass was left quite wild, and I now find that the *Gentians* are dead or dying. (Possibly fine turf would have suited them better.) At the same time I put similar plants close by in the rock garden with *Thymus Serpyllum* in the place of grass. This has proved a great success,

myself, have no heated greenhouse, why I like "some" weeds. I should often be "hard up" for that variety in foliage which gives so much grace to cut flowers if I did not have recourse to "weeds." One of the most delightful is Milk Spurge. A china bowl filled with this is charming with most flowers. Then there is the Filmy Ferny foliage of Fool's Parsley. Young leaves of this or of Hemlock are admirable with the pink double Anemones which come to us from France. At the present time of year whole plants of Chickweed and Speedwell bodily uprooted make a pleasant change from moss as a carpet for flowers. The reddish, frost-nipped tips of Dead Nettle are lasting and effective. The wiry sprays of the little Nippewort (*Lapsana communis*) are as good as, or better than, *Gypsophila* for the foundation of a bouquet in trumpet vases. These are "some" of the weeds I allow in the far corners of my cottage garden.—ANNI AMATEUR.

How to Plant *Crinum Powellii*.—In answer to "Enquirer," page 594 of THE GARDEN for December 12, as to how *Crinums* are grown at Burford, I may say they are planted from 2 feet to 3 feet deep in the ground. After they are cut down by the first frost, we cut the tops quite level with the

the stem is useless for firewood, as I found some three years since, when I had two trees some thirty feet high cut down. I thought then, as perhaps some of your readers have done, that it would be of service in the form of logs, but I was never more disappointed. Although I tried some pieces of the tree in my house a year or so after it was cut down, I could not burn it. It smouldered in a very hot fire, but it would not burn and give out heat.—OBSERVER.

Ivy Under Large Trees.—I was much interested in the splendid illustration, showing Ivy under a large tree, in your issue of December 12, page 599. Under many large trees, especially those of Firs, Cedars and conifers generally, it is often found to be a difficult matter to get a nice green carpet of grasses; then a substitute must be found. In one case I had to form a border to a drive under large trees, with a fine undergrowth of evergreen and deciduous shrubs, and the most successful plant was the Ivy. Between stone kerbs a nice band of Ivy, 1 foot wide, was planted, and the shoots also pegged down in good loam in which some old mortar rubble was incorporated. A little trimming was all that was required afterwards. I have used Periwinkle plants with equal success under single specimens of large trees, as shown in the illustration referred to, and their lovely blue flowers added much to their attractive appearance.—G. GARNER.

— On page 599 is a picture of a large tree with an under-planting of Ivy. It is a beautiful tree with a beautiful trunk, and you know that, if you could see them, its buttress roots would be beautiful too. Over these roots some heathen has put a blanket of Ivy, and to call attention to its hideousness he has made the blanket the same shape as the last bed he planted with Geraniums and Lobelias, and has clipped it neatly round the edges with a pair of shears. I know my GARDEN, and I turned with pleasure to the article, certain that I should read a poetical and fervid description of the beauty of the buttress roots of a great tree, their mossy coverings and the bare brown earth between them; of how, if the soil be kindly, Cyclamens flourish there, and how, further out, under the branches, Daffodils riot in the spring. To my incredulous astonishment I found that the picture was not intended as an awful warning, but as a pattern immediately to be copied "in a good many private gardens and public parks." I think the picture can be trusted to prevent anybody doing so.—E. T. ENGLAND, *Exeter School, Exeter*. [We publish the foregoing, as it is our policy to give both sides of any debatable question. While agreeing with our correspondent that the buttress roots of a tree are beautiful, and that various bulbous plants thrive under the branches of some trees, there are certain positions, more especially in public gardens and parks, where either bare earth or such bulbous plants are impracticable. In such places Ivy is quite a good covering, as anyone may see in the famous Gardens at Kew, where several trees are under-planted in this way.—ED.]

THE OUTDOOR GARDEN AT CHRISTMAS.

TO the uninitiated and unobservant, there are few more dreary or uninteresting places at the festive season than the outdoor garden; but for those who have eyes to see and sufficient knowledge of plant and animal life to appreciate Nature in all her captious moods, the outdoor garden is interesting at all seasons. It is true that those plants which gladdened our hearts during the variable days of spring, the heyday of summer, or later on in the waning months of the year, have descended to a well-earned repose, and it is equally true that the damp, dull days which are so plentiful at this season do not tempt us abroad so alluringly as do the halcyon days of May or June. But if we forsake our gardens, as I fear too many do, with the waning of October, we lose more pleasure than many would believe.

Apart from the plants that may be legitimately expected to give us flowers outdoors at Christmas,

and which will certainly continue until then, unless severe and sudden frost puts a check on their levity. These are, however, but the pleasant surprise-packets of the outdoor garden at Christmas, and although they may, with doubtless many others, be found in several gardens this year, it is not always that we can enjoy them at so late a date. Of those plants which we may expect, even in severe winters, to find flowering now, there is a goodly host. It is true that their beauty is not of the garish kind that we associate with plants of the more favourable seasons, but that it is a beauty quite in keeping with the dull mood of Dame Nature herself, none, I think, will deny. Who, for instance, can fail to appreciate the graceful, pale green catkins that the male plant of *Garrya elliptica* is carrying just now? Yet were we to see this shrub bedecked with catkins in the more bounteous and sunny days, we should probably pass it by as a thing of but little account. Our appreciation of flowers is, after all, one of proportion and environment. Give us plenty under pleasant conditions, and we love only the best; give us a few under a sombre sky and

CATKINS OF THE MALE PLANT OF *GARRYA ELLIPTICA*. THIS IS A BEAUTIFUL SHRUB AT CHRISTMAS.

there is always the possibility, particularly in a mild and open season such as the present, that stray blossoms of many kinds can be culled for the house. Wallflowers of the Early Paris type, Monthly and other China Roses, St. Brigid Anemones, Polyanthus in many hues, double Daisies, the large Snowdrop known as *Galanthus Elwesii*, which this year is flowering quite out of season, and, most appreciated of all, some delightfully sweet Mignonette, are a few of these out-of-season flowers that the writer has in blossom in quite an open garden some days before Christmas,

amid dismal surroundings, and we love them all. It is, perhaps, well that it should be so. Winter Jasmine and Winter Sweet, *Laurustinus* and *Virginian Witch Hazel*, *Lonicera Standishii*, a Honeysuckle with fragrant, twin flowers of dirty white hue; the Glastonbury Thorn and Gorse are all large shrubs or trees that give us their flowers at this season; yet were they to flower at any other time of the year, the majority would be regarded as of little account.

Of more lowly stature are the Crocuses *Imperati* and *lavigatus*; *Iris reticulata*, *I. stylosa*, *I. alata*,

YUCCAS AND OTHER FOLIAGE PLANTS IN MIDWINTER.

Christmas Roses, Winter Aconites (the first of which are just opening); Cyclamen Coum, the dainty little *Scilla sibirica*, and the rosy-looking, bud-bedecked plants of *Ericas carnea* and *mediterranea hybrida*, to say nothing of some late flowers of that low-growing and little-known shrub *Polygala Chamæbuxus*.

But flowers are not the only interesting things in the outdoor garden at Christmas. The many fruits that have this year been produced in such bounteous array do much to dispel gloom and to gladden the heart of the enthusiast. For does not each little crimson or yellow berry contain wonderful possibilities? Take the crimson haw on the Thorn tree, or the more brilliant and rounded berry on the Holly. Each, providing Nature is kind to it, is capable of forming a tree equal in every way to its parent. Their present beauty is a mere detail in their mission in life, a mission that, alas! the majority are, for some inexplicable reason, never allowed to fulfil. Yet the possibility is there, and the knowledge of that fact cannot but lend additional interest to our berried plants as we see them in the outdoor garden at Christmas. Cotoneasters, such as *frigida*, *Simonsii* and *rotundifolia*; the Sea Buckthorn, with its pale orange, semi-transparent berries; the Snowberry, with glistening white fruits; wild and other Rose hews to which the weather has been kind; the pearl-like fruits of Mistletoe, and the pink ones of the lovely Prickly Heath, are but a few of the many that add their quota of brightness, beauty and interest to the outdoor garden just now.

Even though we had no flowers and no berries in our gardens at Christmas, there would still be plenty to interest those who can appreciate beauty of a more humble kind. What, for instance, can be more effective than bold groups of yellow or red stemmed Willows and Dogwoods, planted by the water-side for preference, or in some prominent place in the landscape? In the summer and autumn days, when their leaves are present

and the colour is forming, we give them scant attention; but now that the surroundings are dull we appreciate the bright patches of colour that they create. Then there are the white-stemmed Brambles, curious, lank-looking objects that appear to have been whitewashed and which must be seen by moonlight to be fully appreciated.

Several of the hardy Bamboos, particularly *Bambusa Métake*, are also interesting, their delicate green foliage and glistening stems making a pleasing feature in the outdoor garden. Yuccas, with their bold, fleshy leaves, the Golden Euonymuses and Yews, the glaucous tints of Cedars and Pines, Lavender, Pinks and Cotton Lavender, and the beautiful green of the Mossy Saxifrages, are all objects of quiet beauty that, under more favourable circumstances, would pass unnoticed. The silver stems of Birches, the gnarled trunks of old Oak and other trees, and the graceful outlines of those of weeping habit are all fully revealed to us now that Nature has stripped them of their summer garb.

All the foregoing are but external features, perhaps the only ones that really matter to many who appreciate their gardens solely for the flowers, fruits and stems that flourish therein. But for the enthusiastic cultivator there is still further interest and pleasure in literally getting to the root of things. Surely the originator of that hackneyed phrase, "get to the root of the matter," must have been a gardener of the first water. For getting at the roots of our plants there is no time like a spell of mild weather in winter. But what a shock, albeit an interesting one, awaits us when we do get there! Can it be possible that those ugly, gnarled roots are at one and the same time the feet and mouths of those dainty flowers that charmed us so fully in the sunny days of spring or summer? If Nature were, as some would have us believe, always harmonious, we should expect something quite different, something more in keeping with the delicate beauty

of stems, leaves and flowers that we see above ground. But Nature is, first and foremost, severely practical, though she may try to hoodwink us with beautiful and sweetly scented flowers, which are, after all, but a phase in her ordering of things, and not, as we would fain imagine, solely for our delectation. If, in walking round the outdoor garden at Christmas, we bear in mind that the apparent bareness is but a passing event, and look for and appreciate those things of beauty which are still there, we shall have gained some knowledge and pleasure that the cheeriest of firesides could not yield.

F. W. H.

THE CHRISTMAS & LENTEN ROSES.

THESE bold flowers, popularly known as Christmas and Lenten Roses, from their resemblance to a single Rose and time of flowering, are of singular beauty and a great asset to the border and shrubbery, giving bright relief to the dulness of the garden

during the winter months. They thrive in most garden soils with very little attention, and prefer to be left undisturbed. When it is necessary to transplant them, the best time for doing the work is in spring. [? Ed.] A dressing of well-rotted manure will be found very beneficial and should be applied in March; though we are advised not to use manure in the short treatise on *Helleborus niger* in the *Botanical Magazine*, where there is also a very good plate of this variety (Plate 8). *Helleborus niger*, the Christmas Rose, is an interesting plant, and was much esteemed in the past on account of the medicinal properties it contains; and although it has now been deleted from the British Pharmacopœia, it is still used to a slight extent in homeopathy. Legend says that it was with this plant that Melampus, the Greek seer, healed the three beautiful daughters of King Proetus, who had been stricken with madness by the goddess Hera for their haughtiness in not joining in the worship of that almighty spouse of Zeus. We should like to believe that *H. niger* was a reliable specific for madness, but Gerard's description of its "vertues" hardly invites us to put it to the test. He says: "Black Hellebore purgeth downwards flegme, choler and also Black Choler especially and all melancholike humors, yet not without trouble and difficultie. Therefore it is not to be given but to robustious and strong bodies as Mesues teacheth. A purgation of Black Hellebore is good for mad and furious men, for Lepers, for them that are sick of quartaine ague and briefly for all those that are troubled with black choler and molested with melancholie."

It is probable that the Greeks made large use of this plant because it luxuriates in the woods and hills of Greece. *H. niger* is an alpine plant, and grows on the Apennines, in Italy, Greece and Southern Europe generally. It seems likely that this plant was introduced into this country from Holland and brought with it the name of

"Christ's Rose," as it was called in high Dutch "Christwurz," that is, Christ's Wort or Herb; and in low Dutch "Heylich Kerft Cruit," because it flowered at the time of the birth of Our Lord Jesus Christ. All authorities seem to agree that it was introduced into this country in 1596, though no name of the introducer can be traced, and it is possible that this date is incorrect and may have been copied by one and another, for Gerard, in his "Herbal" (1597), speaks of this variety as though not uncommon round London. It therefore seems likely that it may have been introduced before 1596, as the compiling and printing of Gerard's book must have occupied some years. *H. niger* is so called from the fact that its roots are blackish.

The chief other varieties of *Helleborus* are *abchasicus*, green or purplish; *atrorubens*, dark red; *caucasicus*, pale green, and a variety of this known as *punctatus* (dotted), which is very fine; *colchicus*, bright purple, and *c. coccineus*, bright scarlet; *foetidus*, green; *lividus*, pale green; *odorus*, green and sweet-scented; *olympicus*, purplish; *viridis*, bright green; and *venosus*, purple, veined.

Helleborus orientalis, the Lenten Rose, has large rosy flowers, often four or five on a stem. Many very fine hybrids have been raised from this species.

Clumps of *H. niger* or the *orientalis* varieties will force well, but must only be placed in gentle heat—a cold frame will be sufficient; and it is quite worth the little extra trouble involved, for the blooms will come out beautifully clean, instead of being splashed with mud and battered by the rough weather. They will also be slightly longer in the stem, which is an advantage. G. N. BUNYARD.

THE VALUE OF TRENCHING SOIL.

THE trenching of all vacant plots should proceed as fast as possible during dry weather. Where the soil is heavy and retentive of moisture, it is not wise to tread upon it, even for the purpose of trenching, when in a wet condition unless boards are used to stand upon. Treading kneads the surface too much, thus preventing the proper amelioration of the soil by weather influences. I am a strong advocate of trenching ground annually, or certainly in alternate years. The soil then resists drought so much better during the summer and is so much more easily manipulated and improved generally. The expense of trenching stiff soil too often prevents it being done, but it pays to do it thoroughly. Soil of a light loamy or sandy character does not need trenching; deep digging, with abundant supplies of manure, are all that is necessary to obtain satisfactory results from such soil.

Next to clay, the most difficult soil to manage is that which is heavy, yet not actual clay, some 15 inches or so in depth, overlying a hard, pan-like subsoil of clay and stones firmly embedded. In its natural condition the water from excessive rains cannot percolate through this subsoil for some time, and thus the surface soil remains

waterlogged too long—a condition quite unsuited to plant-life. Such soil can only be treated properly and advantageously by trenching some 2 feet or, better still, 3 feet deep. The method of trenching such soil is open to various opinions. Some writers advocate bringing the lower stratum or subsoil to the surface. To bring such soil to the surface and to leave it there without any addition would entail many difficulties in sowing seeds and planting various crops the first season. If, however, sufficient material, such as decayed vegetable and roadside refuse, leaves, old potting soil, sand and wood ashes, with a small quantity of dry, unslaked lime, can be had to cover the plot 6 inches or so thick previous to sowing or planting the first crop, then I advise the adoption of such a method as bringing to the surface the bottom spit of soil, especially if the plot can be retrenched again the next season. By this method the top and bottom soil will become thoroughly incorporated and improved.

If, however, there is no possibility of obtaining such material, I do not advise bringing the subsoil to the surface. The alternative method is to trench the same depth, but to leave the bottom spit of soil in its present position. When trenching soil of a heavy character, a helpful addition would be a plentiful supply of long strawy manure, freshly gathered leaves or partly decayed vegetable matter. Material of this kind in the bottom trench facilitates quick drainage, and in the near future, when decayed and incorporated with the soil by secondary trenching, provides valuable plant food, apart from its value in ameliorating the soil. I need hardly say that the bottom of the trench should be thoroughly broken up to assist rapid drainage. As trenching proceeds, the soil should be laid up as lightly as possible, especially on the surface, with a view to exposing as large an area as possible to the influence of the weather.

Swanmore.

E. MOLYNEUX.

ROSE-GROWING IN TOWN GARDENS.

THERE is some diversity of opinion as to whether the manuring of Rose-beds in autumn and winter is beneficial or the reverse. The case against it is chiefly that if applied at this time of the year, some of the manurial elements will have become washed out and lost before the roots are able to take advantage of them in the spring, and also that the manure becomes sodden and is likely to prove harmful to the roots and stems of plants during a frost. The latter consideration need hardly deter one, for although it is obvious that plants would suffer from having the substance in actual contact with the stems, those who apply it carefully will see that this does not occur. As regards the roots, a mulch, even of the wettest kind, affords some protection in cold weather, and frost will not penetrate so far into the earth beneath as it would if this were uncovered.

The chief factor which should be taken into consideration is the character of the soil, for no opportunity should be lost of improving its texture. If this be of a light character, therefore, one may safely give a heavy dressing of cow-manure now, but before doing this the soil should be raked up a little around each plant so as to cover about two inches of the basal growths, and this is advisable whether manuring or not.

The manure should be heaped rather than spread between the rows, keeping it well away from the plants. One great advantage of this winter application is that the manure will have become deodorised by the spring, and it will then have rotted sufficiently to be broken up with the hoe. There is no occasion to treat heavy soils in this way, but all will benefit from a dressing of bone-meal and sulphate of potash (three parts

A WINTER SCENE IN THE BAMBOO GARDEN AT KEW

of the former to one of the latter). Bone-meal is a fertiliser that is slow in action, requiring some time to become available as a food supply, while the potash will remain in the soil until taken up by the roots, so that there is considerable benefit in applying both early.

When burning the garden rubbish from time to time, one should bear in mind that the ashes form a valuable manure. Wood-ashes can be added to light soils at the rate of half a pound to the square yard, and if a sufficient quantity is available, sulphate of potash will not be required. Light soils will also benefit considerably by an application of pulverised chalk, which can be applied now, and subsequently hoed in early in spring. This is the most advantageous way of adding lime, in which such land is generally deficient, as it also helps to retain moisture. A pound to the square yard should be the quantity given.

Before planting new Roses or replanting old ones, the roots ought to be carefully examined, and thick ones that are without fibre should be shortened, at the same time removing all those that are dead or damaged. When doing this, one can keep a look-out for suckers and cut out all eyes that are forming upon the stock, which will save considerable trouble later.

P. L. GODDARD.

ROSES ON OLD FRUIT TREES.

It frequently happens that one has an old fruit tree that is past its best, and yet one does not wish to root it out entirely. Few conceive what labour is needed to properly grub out such a plant, and it might often be put to great use and beauty by the help of a few judiciously selected climbers. Among these I know of none better than Clematises and Roses.

At the outset we have ideal ground for the plants to occupy in the most artistic manner. The support, too, is far sounder than we could possibly secure artificially without much expense and labour. Now, far too many err in planting without sufficient preparation in these cases. Remember, the established tree has possession, and whatever else is placed at its base is very heavily handicapped. Therefore we need to take away some of the soil to a good depth and replace it with really good compost, more especially as the older soil must be exhausted. Nor is it quite enough to do this; it is better to sink a small barrel or tub, minus the bottom, and fill this in with some of the better compost. It only remains for me to name a few of the Roses most suitable, and any reader can get to work. *Félicité Perpétue* and *Paul's Single White* are two good whites; *Hiawatha*, *Dorothy Perkins* and *Reine Olga de Wurtemberg*, reds; *Robert Craig*, *Gardenia* and *Alberic Barbier*, yellows; *Elise Robichon*, *Euphrosyne* and *Blush Rambler*, pinks. A. P.

GOLDEN-LEAVED CONIFERS FOR WINTER EFFECTS.

THE various golden-leaved conifers are useful subjects for decorative gardening and may be used for a variety of purposes. Unfortunately, some of the more delicate-constituted ones cannot be grown with success in the

vicinity of large towns and cities, where the atmosphere is rendered impure through smoke or chemical fumes, and even those which grow moderately well under these conditions are shorn of much of their beauty by the coating of dirt

into notice. Some of the best are *aurea variegata*, *Barronii*, *adpressa aurea*, *elegantissima*, *Dovastonii*, *aureo-variegata*, *fastigiata aurea* and *f. Standishii*. The variety *Barronii* is specially worthy of notice on account of the rich coppery colour of the leaves, while *elegantissima* and *Dovastonii aurea* are remarkably graceful in appearance; *adpressa aurea* is of very neat habit with tiny leaves, while the *fastigiata* varieties are golden forms of the Irish Yew.

Next in importance to the Yews are the varieties of *Cupressus*. Of *C. lawsoniana* the variety *lutea* has golden foliage and is of similar habit to the type; *gracilis aurea* is remarkable for its graceful appearance, the secondary branches being pendulous. A golden variety is known of *C. nootkatensis*, while of *Cupressus* (or *Retinospora*) *obtusa* there are several varieties. *Crippsii*, a form of the last named, is a particularly rich-coloured variety of *aurea*, while *gracilis aurea* is of very dainty appearance. *C. pisifera* provides us with several good golden varieties, *plumosa aurea* and *filifera aurea* being the best. *C. macrocarpa lutea* is a vigorous-growing variety of the Monterey Cypress, remarkable for its rich colour during summer and autumn, and its change to a greener tint during late winter and spring. It is an excellent subject, especially for gardens in the vicinity of the coast. The common American *Arbor-vitæ* (*Thuya occidentalis*) provides several golden varieties, that called *lutea* being the best. Of *Thuya plicata* there is a variety *aurea*, and another, *zebrina*; the latter has green and golden-marked shoots. The Chinese *Arbor-vitæ* (*Thuya orientalis*) provides a golden variety named *aurea*, which is a neat-growing plant. *Juniperus chinensis aurea* is a pretty golden variety of the Chinese Juniper, while among Pines we get a golden variety of the common Scots Pine (*Pinus sylvestris*).

In addition to these there are numerous varieties with more or less variegated foliage, but they are inferior to those here mentioned for general work. Some of them have a diseased appearance and the golden patches die

ROSE PAUL'S SINGLE WHITE GROWING OVER AN OLD FRUIT TREE. THE LATTER FORMS AN EXCELLENT SUPPORT.

which collects on the leaves during winter. Under better conditions, however, in a purer atmosphere and away from smoke, where the branches and leaves keep clean, they are most effective, and the colour keeps good for the greater part of the year.

Perhaps of the golden-leaved conifers the various Yews, varieties of *Taxus baccata*, are the most useful, for they thrive in most gardens even about towns. The leaves keep a good colour for many months, and only become dull for a short period previous to new ones being formed. As a rule the brightest colour is found on the under sides of the leaves, but, as they usually turn upwards, the colour is brought prominently

out. Those to which prominence has been given are, in almost all cases, strictly golden coloured, and the plants present a perfectly healthy appearance, being, except in colour, exact counterparts of their respective types, as easy to cultivate, and growing at about the same rate.

Of course, it is desirable and necessary that the soil should be thoroughly prepared before planting, and, if at all poor, some well-decayed manure should be added to the bottom spit. For most evergreens, and this applies equally to those with golden foliage, early autumn—i.e. about the middle or end of September—or the end of March and during April are the best times for planting.

PERPETUAL-FLOWERING PINK PROGRESS.

INTRODUCED in 1909, this beautiful variety has not yet enjoyed the popularity which it deserves, and the only reason I can think of is that it is not sufficiently well known, as any friends who have seen it growing in my greenhouse have been charmed with it, and many indeed are the cuttings which I have given away. Its growth is much more similar to that of a Carnation than of a Pink, but the foliage, being thin and wiry, but exceptionally strong and healthy, closely resembles that of the common Pink. The bloom is most exquisitely formed, and is of a rosy mauve colour. It is, however, a colour which does not blend at all well with most others, but a vase by itself is a sight not to be forgotten. The calyx is not quite what it might be, and I have had some trouble with this splitting, but any defects are amply recompensed by the glorious perfume which, in my opinion, is the feature of Progress. It has the real Clove scent of the old common Pink, and a bunch of cut blooms fills the whole room with a sweet, refreshing odour which few, if any, flowers can excel. Having a hardy constitution, it can be successfully flowered outside or under glass, and in the latter case makes an ideal pot plant. In common with all other Pinks, either cuttings or layers root easily, and as a lot of "grass" is produced, a large stock is very quickly got together. It is not at all difficult to grow well, and I have found the following method of treatment very successful. In August I plant the cuttings in a cold frame in very sandy soil, and when well rooted they are potted into 3-inch pots and replaced in the frame, where they remain all the winter. For the first potting a light compost consisting of two parts light loam, one part leaf-mould and a good sprinkling of coarse sand is best. They will require very little water during the winter months, and are much safer if kept on the dry side. In early spring repot into 5-inch pots, using a heavier compost than for the first potting. Two parts good fibrous loam, one part well-rotted manure, half a part good leaf-mould and a little bone-meal and old mortar-rubble make an ideal medium for this potting. After repotting, the young plants may be left for a few weeks in the cold frame, and then transferred to their growing quarters in the greenhouse, which should be light and airy. If green fly attacks the shoots, irrigate with some good compound whenever the first fly is detected. When the flowers are over, remove as much as possible of the old spent soil and repot into 6-inch or 7-inch pots, using the same compost as before. They will soon start again into growth, and the following season make grand specimen plants either for conservatory decoration or for giving quantities of cut bloom for the house. To enable these two year old plants to yield large blooms, it is advisable to give copious supplies of very weak liquid manure when the flower-buds appear.

Shure.

G. B.

THE ORIGIN AND MEANING OF CHURCH DECORA- TIONS AT CHRISTMAS.

THINK there is very little doubt that one of our oldest and most general customs is that of decorating our churches with evergreens, berries and flowers at the season of Christmas. Pre-reformation or post-reformation, evangelical times or catholic revival, town or country, made only a difference in degree. Wordsworth, John Gay and Robert Herrick, to mention three poets of different ages whose knowledge of country ways and doings is proverbial; Samuel Pepys and John Evelyn, the diarists of Cromwellian and Stewartian times; the fifteenth century congregation of St. Mary-at-Hill in the City of London (as we know from their own or from other written

Our own feelings are sufficient to account for the origin of the practice. There is a seemliness in making the external correspond to the inward on occasions of joy and grief. There is something in the fitness of things that connects decorations and best clothes with days of peculiar importance or the entertaining of guests. It is this, for example, which must have suggested the parable of "The Wedding Garment" to Our Lord, and which must have made its meaning so clear to His hearers. Hence we can see why Christmas has always been associated in the minds of Christians with outward signs of joy both in their homes and in their churches. Impossible but that it should be so. Why, though, Holly and Ivy? What gives these two plants their peculiar position, more especially the first? Two explanations are offered: First, it may be a relic of the old heathen festival of the Saturnalia, which happened to be celebrated at Rome about

A FINE SPECIMEN OF WEEPING HOLLY.

contemporary evidence); all saw their churches decorated for the birthday of Our Lord, and although it is only a surmise, it is well within the bounds of probability if I suggest that the Venerable Bede, Bishop Swithun, Alban the Martyr, or Becket, the murdered archbishop, must also have seen the same emblems of joy and love when they entered God's House on a Christmas morning. Undoubtedly Holly and Ivy are the two plants which always have been, and which still are, associated more than any others with the Nativity. Although the orderly sequence of appropriate and distinctive decorations for the changing seasons has long been a dead letter, we would feel there was something missing were we to see none of the familiar leaves and trails somewhere in the wreaths or devices of to-day

"The Holly hitherto did sway;

Let Box now domineere.

Until the dancing Easter-Day

Or Easter's eve appeare."

From Herrick's "Ceremonies for Candlemass Eve"

a week before the Christian Feast of the Nativity. At this time friends gave one another branches of Holly as an expression of their goodwill, along with the presents which it was customary to send. What more natural than to transfer this innocent custom, with its ready-made meaning, to the great festival of the anniversary of Him who came to bring peace on earth and goodwill among men? Or, secondly, its use may have arisen from the practice of the Druids, who invariably hung in and around their dwelling-places bunches of Holly or other evergreens, in order that the spirits of the woods might find a shelter when their customary abodes were leafless and when the weather was particularly severe, as it so often must have been about the time of the old Christmas Day.

In judging which of the above suggestions is the more probable, it is well to bear in mind two facts: One, the universal association of Ivy with Holly as appropriate for Yuletide decorations,

Church accounts for 1486 (St. Mary-at-Hill, London) are extant which include "Holme and Ivy at Christmas eve," and for 1524 (St. Martin Outwich, London), which have "Item: for holy and ivy at Chrystmas." This may possibly be a relic of the Saturnalian times at Rome, when there is very little doubt men were apt to drink "not wisely, but too well," and when it is certain Ivy wreaths, with their supposed power of lessening the intoxicating effects of wine, were in much vogue. The other is the strange fact that the only plant which, as far as I know, is now absolutely taboo in church decorations is the Mistletoe, the sacred plant of the Druids, cut with imposing ceremonies and with golden knives, and of wide renown for its powers of healing. I am, however, a little doubtful if this has invariably been so, for John Gay (early eighteenth century), who was intimately acquainted with rural life, distinctly says in one of his poems that this was so used; thus:

"Christmas, the joyous period of the year,
Now with bright Holly, all the temples strow,
And with Lawrell green, and sacred mistleto."

If Mistletoe was ever admitted as equally suitable with Holly and Ivy as part of the Christmas adornment of our churches, then probably the Druid origin is the true one. If, on the other hand, it was not so, then the Saturnalian is the most likely one, more particularly when the association of Ivy with Holly is so universal. Personally, I favour the Roman origin as being on the whole the more probable.

A word in conclusion about the factors in the Christmas decorations. Nowadays we use everything that comes to our hands. Yew, Box, Laurel, Cupressus and Thuya are more often, I expect, seen than not. But it was not always so. In the days of Herrick the poet (time of Charles I.) there was a certain well-defined sequence of plants which were to be used for the different seasons, and there is no reason to suppose that the rota was not strictly adhered to. He thus writes of house decoration:

"Down with the rosemary and bayes,
Down with the mistleto,
Instead of holly, now upraise,
The greener box, for show.

* * * * *

Then youthful box, which now hath grace
Your houses to renew
Grown old, surrender must his place
Unto the crisped yew.

When yew is out, then Birch comes in,
And many flowers beside,
Both of a fresh and fragrant kine,
To honour Whitsontide."

—From "*Ceremonies for Candlemasse Eve.*"

In another poem on the same subject the poet seems to allude to the old idea of the evergreens being originally put up as shelters for spirits:

"Down with the rosemary, and so
Down with the baies and misletoe;
Down with the holly, ivie, all
Where with ye drest the Christmas hall;
That so the superstitious find
No one least branch there left behind;
For look, how many leaves there be
Neglected there, maids, trust to me,
So many goblins you shall see."

—From "*Ceremony upon Candlemas Eve.*"

From this last quotation it seems possible to suggest a third idea as to the origin of this Christmas custom of decorating churches and houses. With regard to the former, it may be that the Holly and Ivy are direct descendants of Saturnalian times, and came to Britain ready-made, as it were, with Christianity; while, with regard to the latter, the decorations may be but the continuation of what was once universal throughout the land in the days of the Druids. This, at any rate, would account for the use of Mistletoe in houses, while it is never found in churches. Gay's assertion, though, wants explanation.

JOSEPH JACOB.

FRUIT TREES FOR VARIOUS SOILS AND SITUATIONS.

DURING the next six or eight weeks many thousands of young fruit trees will be planted in various parts of the country, some of them with due regard to the general character of the soil and the positions they are to fill, but many without a thought being given to these important and far-reaching details. With the enlightenment that science combined with practice has, during recent years, brought about, the days of haphazard planting ought before this to have gone. Wise and up-to-date market growers give as much attention to the selection of trees for the soil and positions they are to occupy as they do to the actual planting; but many amateurs and not a few gardeners fail to realise that an unwise selection may prove a stumbling-block for many years, if, indeed, it is ever overcome.

By the selection of trees I do not mean the mere selection of varieties of, say, Apples, Pears or Plums. The best sorts are now fairly well known, and although some do better in certain localities than they do in others, the majority can be grown in almost any district that is at all suitable for the cultivation of hardy fruits, providing the right type of tree, grafted or budded on the stock best suited to the soil, is selected. At the outset, before even the character of the soil is studied, the would-be grower must decide what kind of plantation is to be made—whether it is to be one of trees that will take some time to reach a fruitful stage, but when that stage is reached remain in vigorous and cropping condition for a great many years; or whether the trees shall commence to give heavy crops as soon as established, continue to do so for a score or more of years, and then gradually deteriorate; or it may be that a combination of both is desired. Then, again, the positions of more or less isolated trees must be considered. Is a large tree desirable in a certain spot, or is there only room for a dwarf one, or possibly one that has been more or less severely trained into a certain shape?

These points decided, we may safely turn to the character of the soil and ascertain whether it is composed of a preponderance of clay, or whether sand or similar material forms the bulk. With this information fully ascertained, due regard being given to all the points raised, the selection of trees suitable for almost any garden or plantation will not be a difficult task. Nurserymen of to-day are fully alive to the fact that trees of widely different types are required for various purposes, and lay

themselves out to provide any conceivable types that may be asked for.

Assuming, then, that a permanent plantation or orchard of fruit trees is desired, one where the trees will come slowly into the fruiting stage, but last in that condition for a very long period, we must of necessity have soil with a preponderance of clay and of a good depth, then choose half-standard or standard Apples that have been grafted or budded on Crab Apple or seedling Apple stocks or roots, and Pears that have seedling Pear as a stock. On the other hand, should we desire a plantation that is to crop early, and to last only a comparatively short period, Apples grafted or budded on one of the dwarfing Paradise stocks, and Pears on the Quince, ought to be chosen. Both are shallow rooting and have a dwarfing effect on the trees, besides inducing them to crop freely at a very early age. Although these dwarfing stocks are usually recommended for shallow soil overlying gravel or chalk, and where they do give good results, they may also be utilised on soil of a more retentive and deeper character where dwarf, early cropping trees are desired. An orchard to contain a combination of young fruiting and permanent trees should have half on the stocks previously named and half on the dwarf stocks.

For gardens, pyramid or bush trees, or the trained cordons or espaliers, should be on these dwarfing stocks, as the trees are so much more easily kept within reasonable bounds than if grafted on stocks of a more vigorous character. It is in gardens that special care must be taken in the selection of suitable trees. Nothing is more disappointing than to find that a tree, by the time it is cropping freely, is occupying too much space; the necessary cutting back will only tend to make matters worse. Then, again, some Pears, notably Beurré Bosc and Brown Beurré, usually give the best results if double grafted, *i.e.*, a more common variety, such as Conseiller de la Cour, is first grafted or budded on a seedling Pear or Quince stock, then, when this has grown sufficiently, it is cut down and one of the choicer varieties named grafted or budded on it. Naturally, this is more expensive than where only a single grafting or budding is necessary; but some of the best nurserymen adopt this method, and it pays to select trees of these varieties that have been treated in this way, even though they cost rather more at the outset.

The cultivation of large fruits such as Apples, Pears, Plums and Cherries as cordons is now well understood in every garden worthy of the name. The system has much to commend it. Not only can a large number be accommodated in a very little space, but they are easily managed and protected, and give good crops of the best quality fruit. During recent years the cultivation of Gooseberries and Red and White Currants as cordons has been more widely adopted, and certainly, in the case of the former fruit, the system is much to be preferred to the old style of bushes, wherein the fruit was difficult of access and frequently became splashed badly by heavy rains. For gardens of limited dimensions, cordon or espalier trees of nearly all kinds are exceedingly valuable, and should certainly be chosen in preference to standards or half-standards grafted or budded on stocks of vigorous habit. The Red and White Currants, and also Gooseberries, are excellent for planting against walls or fences facing north. In positions of this kind the fruit can be kept in good condition until late in the season.

TROJAN.

HISTORICAL NOTES ON THE CARNATION.

ONE of the remarkable things connected with the Carnation as a British flower is its comparative novelty. The name cannot be traced beyond, or, to be correct, not quite till after, the middle of the sixteenth century, when it occurs in a letter printed by Hakluyt, also in the "Arte of Gardening" and in "The Gardeners' Labyrinth," and a little later in Lyte's "Herbal" and Tusser's "Five Hundredth Points." No doubt Carnations of a kind would be known and grown previously under the name of Gilliflowers; but even these must have been rare, for, setting aside the assumption that "Gilofre," which disports itself in a variety of spellings in various ancient poetical pieces, has any connection whatever with the Carnation, being invariably associated with exotic Spices, and clearly the Clove of commerce, masquerading in an Anglified French guise, none of the glosses and vocabularies extending from the tenth to the fifteenth centuries, nor any of the few lists of garden plants which have come down to us of date earlier than the sixteenth century, makes mention of the plant.

This does not prove that the plant was not grown, but is probably due to the fact that plants destitute of economic value, either physically or for other purposes, possessed no interest in the eyes of the utilitarians who compiled these particular manuscripts. Carnation seems to have been confined to London, or at least to the South for a long time, because we find Gilly Flower and July Flower in use, the one in Yorkshire in 1618 descriptive of a number of kinds, and the former in Aberdeen in 1624, when Spalding mentions the plants blooming till very late in that year as something unusual. Parkinson, who retains the name of Gilliflower for a section of Carnations, assures the gentlewomen for whom he wrote that the Old English Carnation was a large double flower of a flesh colour. And we may safely conclude from the character of Parkinson for correctness that the variety he refers to was the prototype of all Carnations. He is borne out by Gerard in the name being a distinctive colour one, and it is also clear that "Carnation" did not to these people convey the idea of a blush skin tint such as it has to-day, but the colour of raw flesh. Hence when we come across the names Carnation - Gilliflower and Carnation - Holyoke, we are sure they mean varieties with red or deep rose flowers.

It was not only for the colour that the word was applied, but Carnation denoted a new type

of bloom, very double and much larger than the Gilliflowers, which were either single or double, with small flowers. Liebauld notes two types of double, one large and one small, in cultivation in the South of France in the mid-sixteenth century, and probably our large Carnation emanated thence. Clusius found yellow and apricot Carnations at Vienna; Poland is mentioned by Gerard as the country whence yellow Carnations were derived, and Italy was at the same period noted for its Carnations. It would be strange indeed in that period of merchant

were freely spurred by the fruit-bearing laterals, and these, scarlet in colour, are distinctly ornamental at this time. The fruits are enclosed in a more or less adhesive calyx, and this, bursting open later and reflexing after the manner of Euonymus, reveals the brilliantly coloured fruits. The species is well adapted for pergolas and such-like places.

Chrysanthemum Richmond.—A "Japanese" variety of American origin, its raiser being Mr. E. G. Hill of Rose and Carnation fame. The colour is rich yellow, the variety of much merit at this late season. Exhibited by Mr. T. Stevenson, gardener to E. Mocatta, Esq., Woburn Place, Addlestone, Surrey.

Euphorbia (Poinsettia) pulcherrima rosea.—The name is suggestive of a charming and useful addition to a small set long held in esteem for its high decorative merit at this season. The crowning glory of the typical kind is the head of brilliant scarlet bracts (leaves), which not infrequently have a diameter of a foot or more. In the new-comer the bracts are rose-coloured, tipped with green as shown, the examples not having reached high perfection. A good novelty and an acquisition. From Messrs. H. B. May and Sons, Edmonton.

Lælio-Cattleya Sir Douglas Haig (Lælio-Cattleya Henry Greenwood × Cattleya Octave Doin).—A handsome and beautiful hybrid, the pure white sepals and petals in fine contrast with a lip whose frontal lobe is wholly coloured ruby crimson of a rich, intense shade, the remainder white with yellow suffusion. The line of demarcation between these colours is fixed by a deliberate line right across the lip in a way we do not remember to have seen before. From Messrs. Sander and Sons, St. Albans.

CULTURAL COMMENDATION.

Luculia gratissima.—Superbly flowered branches of this delightfully fragrant, rarely seen greenhouse shrub were shown by Mr. H. J. Elwes, Colesborne, Cirencester, the cymes or heads of blossoms equal in size to those of a large Hydrangea. Larger individually than is usually seen, the flowers were also of a richer tone of

rose colour than is possible of attainment in the London district at this season of the year. The perfect condition of the foliage also demonstrated ideal surroundings as well as cultural excellence. The species is from the Temperate Himalaya. Its presence at exhibitions or in gardens was far more frequent a quarter of a century ago than is the case to-day.

NEW FRUIT.

Apple Winter Ribston.—In general appearance this may be likened to a small Blenheim Orange, and, having the brisk flavour of Ribston Pippin, possesses an assured value at this season of the year. Exhibited by Messrs. George Bunyard and Co., Limited, Maidstone. Award of merit.

The whole of the foregoing awards were made by the Royal Horticultural Society on the 15th inst.

ONE OF THE SPRAYS OF LUCULIA GRATISSIMA SHOWN BY MR. ELWES IN LONDON ON THE 15TH INST.

adventurers were none of these strange and lovely flowers brought home. As we know, they were.

R. P. BROTHERSTON.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Celastrus articulatus.—Fruiting branches of this hardy, deciduous, highly ornamental Japanese climber were shown, and attracted considerable attention by reason of a berry-bearing beauty which it retains for many weeks at this season of the year. The species is now a great attraction at Kew, whence the examples came. The exhibited branches, of the size of an ordinary Cedar-wood pencil and tapering to a fine point,

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Under Glass.

Early Peaches and Nectarines.—Very careful attention will be necessary now in regard to trees which are in bloom, as during dull weather any extra excitement would be injurious. A night temperature of 55° will suit them well, and while the weather is favourable the top ventilators may be left slightly open. When the flowers are fully open, some means should be adopted to distribute the pollen, either by shaking the trees or by means of a soft brush, which must be very carefully applied. A bunch of soft, dry feathers will answer the purpose well.

Late Peach Trees.—These should be pruned, washed and tied into position with as little delay as possible, allowing a space of at least 4 inches between the young shoots, and a clear outlet for the terminal bud to make headway without crossing other shoots. Examine the borders, and if they are at all dry, give a good soaking of clear, soft water. If the roots are near the surface, a top-dressing of loam and bone-meal may be applied with advantage.

Plants Under Glass.

Chrysanthemums.—There should be no delay in propagating the necessary number of plants. The best method is to insert the cuttings singly in small, clean pots, and place them in a slightly heated pit; but if this is not available, they will root quite well in a close, cold frame, although not so quickly. Damping is the greatest trouble in this respect. Keep the stools as hardy as possible, so that the cuttings may be hardy and short-jointed, and avoid long cuttings at all times. It is better practice to propagate the latest varieties now than to allow the cuttings to remain on the old shoots until they become drawn and soft.

The Forcing-House.—In order to keep a full supply of cut flowers during the winter, considerable forethought is necessary with regard to the introduction of the different subjects into heat at the proper time and in sufficient numbers to meet the requirements of the establishment; but it is better practice to commence a few days earlier than to drive this off too late, when hard forcing has to be carried on, with unsatisfactory results. Newly potted shrubs for forcing should be gradually accustomed to heat, and not placed in the forcing-house at once. In this case a temperature of 55° is quite sufficient to start with, providing the start is made early enough.

Humea elegans.—These plants require very careful watering during the winter; a temperature of 50° is quite high enough by night, and the top ventilators should be left open whenever the weather is favourable. Young plants in small pots must not be allowed to become stunted for the want of potting, but a very small shift is all that is necessary for the present. These plants may be given a temperature of 55° after potting.

Freesia refracta alba.—The various batches of these plants must receive attention with regard to support as soon as sufficiently advanced. Keep them growing in a warm greenhouse, and when the pots are well filled with roots, a good supply of weak manure water should be given.

The Flower Garden.

Roses of all kinds should be planted with as little delay as possible after the soil is in a fit state, and if sharp frost sets in, all tender varieties should receive protection.

Lily of the Valley.—Old-established beds of Lily of the Valley will benefit by a top-dressing of fine leaf-soil and thoroughly decayed manure; and if the space between the rows permits, the soil may be lightly pricked up with the point of a digging-fork previous to applying the top-dressing. If new plantations are contemplated, a somewhat shady situation should be selected for them. The ground must be trenched and manured, and if the nature of the soil is too retentive, a quantity of river sand and old lime rubble should be mixed with it.

The Rock Garden.—Plants in frames should be freely ventilated during open weather, the lights only being necessary as a protection from heavy rain or sharp frost, when they should be closed and some covering applied to keep the pots from being

frozen. Any alterations necessary to the rock-work should be pushed forward while the weather is open, so that, when the time for planting arrives, there may be no delay with this important work.

The Kitchen Garden.

Mushrooms.—Continue to collect and prepare manure for new Mushroom-beds. At this season there should be no difficulty in producing Mushrooms within six weeks from the date of spawning the beds; but it is very important that the material is in good condition when the beds are made up. The manure should be placed in a dry situation where plenty of fresh air is available; turn it frequently to avoid sourness, which is the cause of many failures. The house from which supplies are being gathered should be maintained about 55°. The atmosphere may be kept moist by frequently damping the walls and floor of the house.

Potatoes.—Tubers for planting should be selected now and placed singly in shallow trays or boxes; for early plantations in pots and boxes the sets may be placed in gentle heat to sprout, after which the pots should be prepared. Ten-inch pots should be freely crocked, and three parts filled with sandy loam and leaf-soil in equal quantities. The tubers should then be placed in position, three to each pot. A temperature of 50° is quite high enough, and when the young shoots are through the surface, the pots should be raised to within a few inches of the roof glass. As growth advances, ventilation must be freely given.

Early Peas.—In sheltered gardens a sowing of Peas may be made on a warm south border about the end of the year, providing the soil is not too wet. At Frogmore our first sowing was made last year on December 30, and gathering commenced on June 2. From that date an unbroken daily supply was kept up till November 11. The variety for first sowing must be hardy, and for this purpose I find *The Pilot* without an equal. The pods are as large as those of *Gradus*, and the quality of the produce is all that can be desired.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Salads.—Continue to sow Mustard and Cress and Radishes at intervals, the former in boxes, but the latter will do better in a warm frame. Fresh batches of Endive should also be got under cover for blanching purposes, and any plants that may still be in the open ought to be protected with straw. A small sowing of Lettuce should now be made, and as growth will be very slow at this time, the plants must not be unduly forced. Earlier batches growing in frames should have the soil stirred between the plants, and all decayed leaves at once removed.

Celery.—Opportunity should be taken on fine days to lift a quantity of roots for immediate use, as, if the ground becomes frost-bound, it is by no means an easy matter to take up the required number each day. If these are stood in a cool shed among ashes or sand, they will keep perfectly fresh for some time.

The Seed Order.—As every post will now be bringing in the new season's catalogues, it will be wise during the long evenings to study these before making out the order, as even to the most experienced the final making up of the order requires careful study. This difficulty is increased where the order is selected from, say, half a dozen different firms. It is always wise to try some of the novelties, or, at any rate, something that has not been hitherto tried; this always gives an added interest to the season's work. Above all, order early, if for no other reason than out of consideration for the seedsmen.

The Flower Garden.

Nymphæas.—These aquatics, although to a certain extent dormant, should by no means be neglected. Sometimes they are planted in tubs or baskets in artificial ponds with no great depth of water, and much damage is sure to result if this becomes frozen to any extent. In such cases it will be advisable to have the ice broken round the

plants at least once a day, if this is possible, and see that the plants are covered by at least a foot of water.

Rheums.—There is perhaps no more striking plant in the bog or wild garden than the various forms of the Ornamental Rhubarb, which associate so well with Gunneras and many other hardy plants. Where planting is intended, this should be completed as soon as possible. The plants grow quite freely in almost any kind of soil, and, once planted, they may be left to take care of themselves.

Trenching in the Flower Garden.—If not already done, the ground to be occupied by Dahlias and Sweet Peas should be deeply dug or trenched without delay. For the latter, our method is to throw out a trench about three feet wide and about the same depth, and let it remain open until the beginning of March, when it can be made up with soil and manure previous to planting. In trenching for Dahlias, a liberal supply of manure should be added to the soil.

Plants Under Glass.

Dracænas.—The older plants that have become somewhat unsightly through the loss of the lower leaves may have the tops taken off; these can be rooted in a bottle containing water and small pieces of charcoal. As soon as roots are emitted, the tops should be potted up and placed for a short period in a propagating-case until they are established. To increase the stock, the stems should be cut into small pieces, and these placed in boxes or pans filled with leaf-mould and sand, where they will root readily.

Amaryllis.—A few of the earliest-ripened bulbs should now be brought from their resting quarters and top-dressed prior to being placed in a moderate temperature. In top-dressing, remove the surface soil, taking care not to damage the roots, and replace this with a mixture of loam, leaf-mould and sand, with the addition of a little dried cow-manure. Very little water will be required for a time; indeed, to overwater them at this stage would cause the bulbs to make growth at the expense of the flower-spikes.

Ferns.—Attention must now be given to the Adiantum section, which will by this time be pretty well devoid of fronds. Those that are decayed should be removed, and if the slightest trace of scale is observed, these fronds should be burnt. Unless the plants are wanted for an early supply, they may still be rested for another month, giving just sufficient water to keep them alive.

The Hardy Fruit Garden.

Trees in Grass.—Where these trees seem to be stunted in growth and otherwise have an unhealthy appearance, it is certain there is something wrong at the roots. In such cases it will be advisable to fork up the grass round the stem of the tree—say, 4 feet all round—and top-dress with a mixture of turfy loam, lime rubble and wood ashes, afterwards applying a light mulch of good farmyard manure.

Planting.—While the weather permits, the planting of all fruit trees must be proceeded with, as any delay might result in the trees being out of the ground for weeks. After being planted, it is of the utmost importance that all trees should be correctly named. This will not only be found of great assistance when gathering the fruits, but also a more intelligent interest will be taken in their cultivation. Opportunity should also be taken to examine the other trees and rename those that require it.

Fruit Under Glass.

Strawberries.—The earliest batch of these will now be commencing to grow, and may be given slight bottom-heat. More than ordinary care must be exercised in applying water to the roots, as, so far as my experience goes, quite as many plants die from an overdose as they do from the other extreme. As a precaution against green fly, it might be as well to fumigate the house, say twice, before the flowers open.

Melons.—A small batch of Melons should now be sown, and as these are essentially sun-loving plants, the greatest care must be exercised in their management in the earlier stages during these sunless days. The seeds should be sown singly in small pots and plunged in a hot-bed, and, as soon as the young plants appear, they must be placed in a position close to the glass, at least during the daytime.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavours to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object makes a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowerin shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

ERADICATING POLYGONUM POLYSTACHYUM (R. H. W.).—The troublesomeness of several species of this genus is due to the fact that they are capable of giving a new plant, not only from every scrap of root, but in course of time from every node of every root; hence their aggressiveness and the difficulty of getting rid of a well-entrenched enemy. In the circumstances, we can only advise you to do what we have more than once been compelled to do with that equally bad pest, Gout-weed, viz., first dig out the whole of the soil of the affected area to a depth of 2½ feet or more, and either treat the bottom with weed killer at double strength or insert a 6-inch-thick layer of gas-lime, leaving the hole open meanwhile and covering the lime with a thin layer of soil to retain the obnoxious fumes. This has the effect of poisoning the soil below and killing any roots which remain. If convenient, discard the excavated soil and substitute it with fresh. If not, spread it out so thinly that it can be overhauled and every vestige of root seen. The former would be the simplest, and probably the least costly too. As the plant has also invaded the path, it might be necessary to treat this on similar lines, otherwise you will be continually confronted by an enemy at front and rear and both flanks as well. In exceptional cases such as this, only the most drastic measures are likely to save the situation. Our sympathies are with you; we know the plant.

ROSE GARDEN.

PRUNING ROSES FIRST SEASON AFTER PLANTING (A. G. S.).—You can retain the Ponzance Briars almost their full length, merely removing the extreme ends of the shoots in March. In subsequent years cut one or more of the oldest growths to the ground each spring. Ramblers of the wichuriana section, such as Dorothy Perkins, need not be pruned the first year, but they would be all the better in subsequent years if cut back to within 6 inches or 8 inches of the soil. Ramblers of the multiflora section, such as Crimson Rambler, cut back to about twelve inches in March. Climbing Teas and Hybrid Teas, prune back to 2 feet in March. Dwarf Teas and Hybrid Teas, prune at the end of March or early April to within 4 inches or 5 inches of the ground, excepting strong growers such as J. B. Clark and George Dickson. These should be retained about twelve inches to fifteen inches long. You need not prune the Honeysuckle or Clematis montana. C. Jackmannii should be cut back to within a foot of the ground each year, unless you wish it to attain a lofty height, in which case do not prune, but you will have no bloom low down. Rose Conrad F. Meyer, prune back to about three feet. In subsequent years retain young growths 4 feet to 5 feet long, and cut out old wood freely close to the ground.

THE GREENHOUSE.

TREATMENT OF PANDANUS VEITCHII (W. H.).—This Pandanus does not require any special treatment

during the winter months, provided a suitable temperature is maintained. We are inclined to think that your trouble is caused by the plants being kept too cold. You say they are kept in a temperature of about 65°. If that is the day temperature, the night may well be 10° lower, and that would be too cold. A minimum night temperature of 60° to 65° is necessary to keep this Pandanus in good condition. If the thermometer is allowed to drop too low during the night, this, combined with an excess of atmospheric moisture, would cause the damage complained of. The soil must, of course, be kept in a regular state of moisture.

FRUIT GARDEN.

FRUIT SPRAYER (E. K. B.).—We think that for general purposes in a small garden a knapsack sprayer with a pump is the most useful, the one you mention being serviceable, but several others advertised in our columns are also good. The best winter wash for cleansing fruit trees is made by dissolving 2lb. of caustic soda in ten gallons of water, but this will not cure Apple scab, and Peach scale is better attacked by a wash containing paraffin. To deal with Apple scab, take care to prune out all the cracked or dead shoots and spurs during the winter, then spray with Bordeaux mixture just before the buds burst, and again just after the petals have fallen.

APPLES ROTTING (F. A. C.).—The Apples appear to have become over-ripe and to have been over-charged with water when they were picked. In seasons when a dry spell is followed by rain, the latter often happens. No fungus or insect pest is, so far as we can see, associated with the trouble.

APPLE FOR INSPECTION (F. B.).—The Apple is apparently attacked by the fungus of brown rot, Sclerotinia fructigena. If it persists in the trees during the winter it will probably kill many of the flowers, and it would therefore be well to spray the trees with Bordeaux mixture just before the buds open in spring. Remove and burn all mummy fruits from the trees.

MISCELLANEOUS.

CATERPILLAR FOR NAMING (Q. W.).—The creature sent is the caterpillar of the swift moth. It attacks and feeds on the roots of various plants, especially fleshy ones like those of the Peony. A soil fumigant might drive it away, but the best preventive is to catch the moths as they flit over the beds in June at dusk. Birds devour the grubs readily when they are turned out in digging, and many are killed through the attack of a fungus.

MOSS ON LAWN (A. W.).—The best treatment for your lawn after raking the moss out will be to give it a good dressing of fine soil at once. This should be raked about well wherever the soil is dry enough, in order that it does not become beaten down. Do not rake it until the grass is really vigorous in spring. A dressing of basic slag and kainit can be applied about the beginning of February at the rate of 3lb. of the former and 1lb. of the latter to the rod. A really good dressing of soil is often efficacious in destroying moss.

NAME OF FRUIT.—E. K.—Ribston Pippin is correct.

BOOKS.

An American View of Garden Design.*—

America has taken to garden design with characteristic vigour. Many of the universities give special courses in landscape and formal design, and Miss Humphreys' book is the outcome of college studies. She discusses and illustrates every sort of equipment and ornament for the garden, and gives some useful advice which needs to be heeded as much in England as in the States. In her catalogue of garden offences, three stand out pre-eminently—the mixture of styles, the mixture of materials, and the overcrowding of features. She justly pleads with the garden-lover not to set a Greek temple in a Japanese garden, not to mingle solid stone ornaments with perishable rustic work, and, above all, to recognise the limitations of space. A garden should not be a museum of styles culled from every country and century, but an organic unity in which every element is justified by the degree in which it contributes to a harmonious whole. Ignorance in any art is a bad thing, but too much knowledge may be worse if it stifles the reticence of careful choice and if it fails to reject details of design not mutually helpful.

* "The Practical Book of Garden Architecture," by Phoebe Weston Humphreys. Lippincott; price 21s.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

COMPARED with the early December meeting, when the great hall of the society at Vincent Square was redolent of fruit and flowers of the finest description, this, the last fortnightly show of the year, held on the 15th inst., was thin indeed, though little below the normal at this season. The outstanding feature was the fine bank of Euphorbias (Poinsettias) from Edmonton, which, in scarlet and rose colours, was most effective. Quite excellent, too, was the well-grown, well-staged lot of Carnations from Hayward's Heath, while winter-flowering Heaths of the soft-wooded section were in more than one direction a great charm. Brilliant masses of Azaleas demonstrated the responsiveness of these flowers to forcing, while Orchids were well displayed by several leading firms. Novelties were not numerous, the floral committee granting awards of merit to three, and the Orchid and the fruit and vegetable committees to one each.

ORCHID COMMITTEE.

Present: J. Gurney Fowler, Esq. (chairman), Sir Harry J. Veitch, and Messrs. J. O'Brien, Gurney Wilson, W. Bolton, R. A. Rolfe, J. Wilson Potter, F. J. Hanbury, A. McBean, Walter Cobb, J. Charlesworth, J. Cypher, W. H. Hatcher, W. P. Bound, J. E. Shill, C. H. Curtis, A. Dye, W. H. White, S. W. Flory and Stuart H. Low.

Messrs. James Cypher and Sons, Exotic Nurseries, Cheltenham, exhibited a superb lot of Cypripediums, the perfect condition of which—freshness, vigour, handsome, well-developed flowers and the like—evidenced ideal surroundings and high cultural excellence not always seen. On the present occasion the choice assortment, which gained a silver Flora medal, contained excellent examples of lecanum Gratrixæ, l. clinkaberryana, the chaste white-flowered Boltonii, Priam (whose handsome coloured dorsal sepal always appeals), Euryades splendens (with rose-coloured dorsal sepal and handsomely developed pouch), Queen Alexandra (which appeals by way of size and fine pink dorsal sepal), together with such indispensable as Thalia, Sanderæ (the queen of the yellow insignes), Harefield Hall (bold and telling) and the beautiful and distinct Actæus Milky Way. These were of outstanding merit.

Messrs. Stuart Low and Co., Enfield, had very beautiful examples of Cattleya Fabia, C. labiata reedleyensis (white, with orange throat), C. l. alba, C. moira rubescens (a very charming bit of colour), the all-white Brasso-Cattleya Queen Alexandra (with heavily fringed lip), B.-C. Maronæ (of a pleasing pink shade), Cypripedium insigne Sanderæ, C. callo-rothschildianum, Oncidium varicosum and Vandas cærulea and sanderiana. Silver Banksian medal.

Messrs. Flory and Black, Langley, had some fine Odontoglossum crispum varieties and the very beautiful Lælio-Cattleya Barbarossa variety (pink sepals and crimson lip) and L.-C. Bola variety (with pinky white sepals and crimson lip), both very charming and quite distinct.

From Baron Bruno Schröder, The Dell, Englefield Green, came a lovely example of Cypripedium Moonbeam (a sturdy-looking plant, with yellow pouch and petals and white, green-shaded dorsal sepal). A freely flowered specimen was shown. Odontoglossum crispum Leonard Perfect was handsome and well grown, and merited the cultural commendation awarded.

Mr. Walter Cobb, Horsham, showed a well-flowered example of Odontoglossum periclitum Cobb's variety, which is very heavily blotched with dark chocolate.

Mr. J. T. Bennett-Poë, Cheshunt, had the very beautiful pink-flowered Brasso-Cattleya Mme. C. Masson, in every way a handsome and distinct hybrid.

Messrs. Sander and Sons, St. Albans, received a silver Flora medal for a beautiful and interesting lot, the more conspicuous being Lælio-Cattleya Bertha Fournier (of rich ruby red tone), L.-C. Phoenix (with greenish sepals and handsome, dark-coloured lip), Brasso-Cattleya Wotan (pink), Odontoglossum cirrhosa ardentissimum (whose pinky ground colour is copiously barred with chocolate), the very dark-coloured, if small-flowered, Odontodia devoniana, the yellow-flowered Lycaste Youngii and Zygopetalum Mackayii.

Messrs. Charlesworth and Co., Hayward's Heath, Sussex, were awarded a silver Flora medal for a group containing many choice things, none, however, of greater outstanding merit than the richly coloured, gracefully arching spikes of Calanthe Veitchii or the handsome, pure white of Miltonia bleuana. Both, too, were in force, and showed well. In addition there were some fine Odontoglossums, notably O. armainvillieriensis xanthotes (with a great arching raceme of pure white flowers) and O. eximium (handsome in size and heavily blotched withal), Lælio-Cattleya Bella alba (white sepals and petals, with crimson purple lip), L.-C. Cornelia (with yellowish sepals, whose crimson lip is also heavily veined), Lælia gouldiana (reddish), the old, though useful, Odontoglossum grande, and the miniature chaste white-flowered Masdevallia tovarensis, with a variety of Cypripediums, were also noted in the group.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), Messrs. E. A. Bowles, J. Green, B. Crisp, R. C. Notcutt, W. J. Bean, G. Reuthe, R. Hooper Pearson, J. Hudson, C. R. Fielder, J. W. Moorman, J. Jennings, W. Howe, C. Dixon, T. Stevenson, J. Dickson, F. W. Harvey, J. T. Bennett-Poë, W. P. Thomson, E. H. Jenkins and G. Paul.

Messrs. H. B. May and Sons, Edmonton, arranged a floor group of well-grown Poinsettias, the examples of 2½ feet high or thereabouts terminated by well-coloured

heads of bracts, making a brilliant display. The arrangement took the form of three semi-circular groups, two of the brilliant *P. pulcherrima*, with a central one of the new *P. p. rosea*, a charming addition to the group. Intervening spaces were occupied by groups of *Erica nivea*, *E. autumnalis*, *E. hyemalis*, *E. h. alba* and others, and while contrasting well with the main feature of the exhibit, also afforded good variety. Begonias of the Gloire de Lorraine set, with Ferns of sorts, constituted a good margin, some beautifully grown specimens of *Areca lutescens* occupying the background. A handsome seasonal group. Silver Flora medal.

Messrs. Wills and Segar, Onslow Crescent, South Kensington, displayed a table of greenhouse flowering plants, of which the soft-wooded Heaths were among the more important. Of these, *E. melanthera*, *E. hyemalis* and *E. nivea* were all in well-flowered bushes and very beautiful at this season of the year. Begonia Gloire de Lorraine and some delightful bushes of Azaleas as full of flower as in May and in one or two varieties also added charm to the group. Orange trees in fruit were also good. Silver Flora medal.

Mr. Clarence Elliott, Stevenage, had a pretty variety of alpines, chiefly of Saxifrages and Sedums, together with flowers of Gentiana and many miniature-growing shrubs suited to rock gardening. Among these, *Camphorosma monspeliensis* was most interesting.

Messrs. Allwood Brothers, Hayward's Heath, had a most delightful gathering of Perpetual-flowering Carnations—certainly one of the most charming and varied staged by this firm during the present season. Among the more beautiful and distinct were Fairmount (heliotrope), Gorgeous (cerise), Mandarin (fancy), Mary Allwood (one of the most shapely of winter-flowering sorts), Peerless (a fine cerise), Mrs. C. F. Raphael, Wivelsfield White (very pure and beautiful), Rosette (deep cerise) and Triumph (deep crimson). Silver Banksian medal.

Mr. G. Reuthe, Keston, set up a variety of hardy plants, chiefly alpines not in flower, though winter-flowering Crocuses were very beautiful. Of these, *C. marathonsius*, *C. laevigatus* (purple and mauve) and *C. hyemalis* were very fine. Iris *Histrio*, white and red *Lapagerias* (cut from the open), Snowdrops and a charming lot of *Erica mediterranea hybrida* were all good.

Messrs. Wells and Co., Limited, Merstham, set up vases of Chrysanthemums, Carnations and the pink-flowered Snapdragon *Nelrose*, the latter very pretty at this season. Of the Carnations, Pink Sensation, Champion (scarlet), Red Benora and Aviator (scarlet) were very good. Chrysanthemum Richmond, rich yellow (see "New and Rare Plants"), was also in this group. Bronze Flora medal.

Messrs. Stuart Low and Co., Enfield, in addition to winter-flowering Begonias, as Optima, Exquisite, Elatior and others, showed Cyclamen in variety and a goodly grouping of *Acacia platyptera*, the latter with globular bosses of flowers. In another direction Messrs. Low staged Carnations of excellent quality, of which Premier (yellow), Triumph (crimson), Satin Robe, Salmon Enchantress, Mrs. Mackay Edgar (fine pink), Mrs. C. F. Raphael (very large), Mary Allwood and Gorgeous (cerise) were the more imposing. The group was most tastefully arranged. Silver Banksian medal.

The Misses Hopkins, Shepperton, showed made-up boxes of alpines similar to those exhibited at the last meeting. They were rather interesting. Gentians, Campanulas, Saxifrages and Sedums were all included.

Messrs. W. Cutbush and Son, Highgate, N., displayed a table group of *Erica hyemalis alba*, *Daphne indica rubra*, Cyclamen in variety, *Erica autumnalis*, Begonia Gloire de Lorraine, together with retarded Lilies and other plants. Silver Banksian medal.

Messrs. J. Piper and Sons, Bayswater, displayed a large table of Azaleas in variety, together with soft-wooded Heaths, handsome Palms, Crotons and Ferns. The exhibit was of an extensive as well as an attractive nature. Silver Flora medal.

Mr. L. R. Russell, Richmond, had a large circular group of Begonia Gloire de Lorraine and its sports, the whole of the plants in well-flowered examples. In another direction Mr. Russell exhibited a big group of chiefly berry-bearing shrubs, as *Skimmia*, *Pernettya mucronata* in variety, *Aucuba vera*, *Arbutus Unedo*, *Crataegus (Pyracantha) angustifolia* (with orange-coloured fruits), *Garrya elliptica* and its variety *femina*, with *Euonymuses*, *Ivies* and other things. Silver Flora medal.

FRUIT AND VEGETABLE COMMITTEE.

Present: A. H. Pearson, Esq. (chairman), and Messrs. J. Cheal, W. J. Jeffries, W. Bates, Edwin Beckett, A. R. Allan, H. Markham, H. J. Wright, E. A. Bunyard, A. Bullock, Owen Thomas, John Harrison, W. Poupert, J. Willard, James Gibson, George Kelf and P. D. Tuckett.

The exhibits before this committee were exceedingly limited, and consisted of dishes of fruits entered for award. The only variety attaining to this honour was Winter Ribston, from Messrs. G. Bunyard and Co., Maidstone. In appearance it favours a small Blenheim, with the brisk flavour of the Ribston. Apple Joffre-French, a highly built, conically inclined, golden-skinned fruit, and Apple Lord Kitchener, having somewhat of the form and size of a Bramley's Seedling, came from Mr. W. Palmer, Andover, Hants. Neither, however, appealed from the attractive point of view, or, judged by results, from the usually applied tests at the table. A tray of fruits of Wellington, showing the spotting to which this excellent late-cooking kind is prone, was also on view. The source whence it came was not displayed.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE executive committee of this society held a meeting on Monday, the 14th inst., at Carr's Restaurant, Mr.

Thomas Bevan presiding. The secretary presented the financial statement, which seemed to give general approval, for it was passed unanimously. All items of expenditure will be paid up to the end of the year out of current receipts, and consequently there will be no necessity, as was anticipated, of falling back on the reserve fund. The accounts and report for 1914 will be printed for circulation at the annual meeting, which will be held at Carr's Restaurant, Strand, on February 1 next at 7 p.m.

It was resolved that the usual shows be held in 1915, at the Crystal Palace if possible; but if not there, it is hoped that the society will be able to make other arrangements. This cannot be decided until it is known how the Crystal Palace may be affected by war requirements. The following are the dates for the meetings of the executive committee next season, viz., September 20, October 18, November 15 and December 13, 1915, and January 17, 1916. The floral committee will meet in 1915 on the dates following: September 20, October 4, 18 and 25, November 3, 15 and 29, and December 8.

On January 13 the floral committee's dinner will be held at the Old Burton Tavern, Cheapside. An invitation is cordially extended to members of the other committees and their friends. Mr. D. B. Crane, as chairman of the floral committee, pointed out that they had had eight meetings, at which no fewer than 103 novelties had been submitted. He felt they would all agree that they had thus helped to keep alive the interest in the Chrysanthemum during a period of exceptional difficulty. Much care had been exercised in making the awards, for to-day a much higher standard of excellence in all sections is demanded. The registration fees amounted to £5 3s., an important addition to the funds of the society.

After an interesting and lively informal discussion concerning singles, disbudded and in spray form, the meeting closed.

CROYDON AND DISTRICT HORTICULTURAL SOCIETY.

"THE Wonders of a Green Leaf" was the title of an illustrated lecture given by Mr. C. H. Curtis before the members of the Croydon and District Horticultural Mutual Improvement Society at their last meeting, held at the Surrey Hotel, George Street. It was as an old friend that Mr. Curtis was received by his audience, for he has met this society on more than one occasion, and his genial manner wins for him the highest esteem from all members of the gardening profession. The casual observer looks upon the green leaf in an uninterested manner. It simply comes within his range of vision, and it has appeared year after year, and will continue to do so as long as the world lasts. But when we stop to consider and search into the important functions they possess for the well-being of mankind, it is then we find the wonderful part the leaves play in the economy of Nature. Among their many uses the principal is as a source of food to man and beast, and the lecturer aptly described their position as standing between living beings and starvation. In other ways they are useful to us, especially in their chemical constituents. The healing medicine concocted from the herbs, or the deadly poison distilled from the leaves, each has its uses for man. Leaves afford shelter for man, beast and bird; they emit a sweet fragrance, and they inhale the carbonic acid gas given off by animals, retaining the carbon for their own nutrition and allowing the oxygen to escape purified. Then, again, how much do they add to the beauty of our landscapes. Remove them and we have a desolate tract. A leaf of a plant illustrates the great forces of energy contained between its cuticles, and energy without noise. Walk through a field of Cabbages composed entirely of leaves, and one can imagine the vast energies displayed in raising itself from the small seed to the matured plant. In Nature's adaptability it has not forgotten the environment of its subjects. For instance, in most of our trees the leaves have a flat surface spread out to catch the sun's rays, an all-powerful element for the well-being of the plant. Leaves are placed one above the other to serve as a means of distributing moisture. It may be noted also that while some leaves turn outwards from the plant, as the Horse Chestnut, there are others which turn towards the main stem, such as the Rhubarb and the Beet. Plants of this class are not branching, and require their moisture nearer to the stem. In arid, dry atmospheres leaves of plants are thicker, like the Cactus. These have their special construction to enable them to conserve moisture for longer periods. The classification of trees is deciduous (trees which cast off their leaves annually) and evergreens. In each illustration on the screen the lecturer showed a picture composed entirely of leaves or leafy plants, pleasing to the sight and restful to the mind. In concluding his discourse, he spoke of the wonders of a green leaf in supplying—in Ruskin's words—"trees for the builder's yard, flowers for the bride's chamber, corn for the granary, moss for the grave."

The audience tendered heartiest thanks to Mr. Curtis for such an excellent lecture. Several exhibits of flowers were staged by Messrs. W. Coles, J. Dingwall, R. Oatley and G. Scrivens, and added interest to the evening.

VALE OF LEVEN AND DUMBARTON HORTICULTURAL ASSOCIATION.

THE PROPAGATION OF PLANTS.

AT the usual monthly meeting of this society, held at the Public Hall, Alexandria, on December 9, Mr. A. Hosking, Horticultural Organiser of the West of Scotland Agricultural College, delivered a most instructive and interesting lecture on "The Propagation of Plants by Seeds, Cuttings, Layers, Budding and Grafting." In the course of his address he said that the propagation of plants was an interesting phase of gardening. In dealing with the

importance of a propagating-house, his remarks were very much enhanced by the diagram which was thrown on the screen, while he also illustrated the principles of a sound and well-built greenhouse. In dealing with seed propagation, Mr. Hosking pointed out the vast difference of seed propagation by Nature and that undergone with the skilled hands of the gardener. In the first instance the seed was, when ripe, blown round and about the original plant and propagated. Instead of having, as before, one plant, a great many had appeared. Such self-sowing plants were a nuisance in some respects as when they are left alone they make the border present an unsightly appearance. The gardener has overcome this nuisance by being able to harvest his seed, thus planting or propagating at his own will. Another item which should not be overlooked is to take care not to overcrowd the seedlings that have been planted in pots or boxes. Overcrowding is detrimental to the plant's growth. Dealing with cuttings, he pointed out the best method to adopt, and with customary care there should be few failures. For instance, with the Honeysuckle, like many more plants, it is advisable to take a half-ripened shoot and strike it in July or August. He next demonstrated the importance of placing a bell-glass over some of the harder-struck cuttings. With *Ericas* this was a good plan to adopt, but care must be exercised in wiping the interior of the bell-glass every day, as a vast amount of moisture collects quickly on the glass. The propagation of leaves was next spoken of, and *Malaxis paludosa* seems to be easily propagated in this way. Severing the leaf from the old plant and planting it in a damp situation, it will in time form itself into a fine plant. Gloxinias can be propagated in a similar manner if the veinwork is cut. Stonecrops, too, if taken with a bud attached to the base of the leaf, will give satisfaction. The layering of Rhododendrons, Carnations, &c., occupied some time to explain. Here mention was made of the importance of serpentine and aerial layering. Budding he termed a mysterious undertaking. He followed these remarks with a splendid and interesting account of splice, saddle, rind and cleft grafting. A brief but interesting inlet into the propagation of corms, tubers, runners or stolons concluded the lecture, which was much appreciated by the audience, and was illustrated with a comprehensive series of lantern slides. Councillor James Parlane, who occupied the chair, expressed the feelings of the audience in according Mr. Hosking a very hearty vote of thanks for his able and valuable lecture.

Mr. James McKenzie, Tullichewan, exhibited a most meritorious group of Chrysanthemums. The group consisted of the pure white form of Purity, Sylvia Slade (rose garnet), the single and beautiful rich pink form of Edith Pagram and the exquisitely blended Market Red. At the close the chairman was accorded a vote of thanks.

At the meeting on January 13 next Mr. Robert Dickson of Messrs. Austin and McAslan, Glasgow, will take for his subject "Some Sources of Nature's Plant Food."

TRADE NOTES.

TREES AND SHRUBS FOR PRESENT PLANTING.

WE are reminded that the present is an excellent time for planting nearly all kinds of trees and shrubs by the receipt of a particularly interesting catalogue from Messrs. Pennell and Sons, the old-established and well-known nursery firm of Lincoln, with branches at Grimsby, Doncaster, Gainsborough and Brigg. This catalogue is replete with information about all kinds of hardy trees and shrubs, including fruit trees, the numerous illustrations being particularly good and most useful as a guide to amateurs. In addition to the best standard varieties of the respective kinds, Messrs. Pennell list a great many of the newest and choicest varieties and species. We advise all our readers who are interested to write to the firm for a free copy of this catalogue.

ROOTS FOR FORCING.

Now that many kinds of vegetable and flower roots are being taken into the forcing-house, we would draw the attention of our readers to the interesting catalogue of such roots published by Messrs. Mann and Sons, Twickenham. This contains particulars and prices of practically all kinds of roots suitable for forcing, a business of which the firm has made a speciality for many years. Gardeners who are short of stock will find in its pages just the material and information they need. To the amateur who wishes to force a few kinds, the excellent practical hints will prove of the greatest value. Messrs. Mann will be pleased to send a copy of this catalogue to anyone who cares to write for it.

PUBLICATIONS RECEIVED.

"The Garden Under Glass," by W. F. Rowles; price 6s. net. Grant Richards, Limited, London.
 "Productive Orcharding," by Fred C. Sears, M.S.; price 6s. net. J. B. Lippincott and Co., Philadelphia and London.
 "A Textbook of Grasses," by A. S. Hitchcock; price 6s. 6d. net. Macmillan and Co., Limited, London and New York.
 "Adventures Among Wild Flowers," by John Trevena; price 7s. 6d. net. Edward Arnold, London.
 "Live Stock Journal Almanack," price 1s. Messrs. Vinton and Co., Limited, 8, Bream's Buildings, Chancery Lane, London, E.C.

* * * The Yearly Subscription to THE GARDEN is: Inland, 6s. 6d.; Foreign, 8s. 9d.
